Methinks that just about every radio, by Motorola and Kenwood have a
transmit timeout timer.
<http://802.11junk.com/jeffl/pics/drivel/slides/too-many-radios.html>
The dip switch programmable radios (SP10) do not have a timer, but
literally every radio that requires a computah to setup has a timer.
Note that I was talking about mobile radios all of which are
programmable, not handhelds.

>Before the public safety services here switched to a digital system,

>(which often consists of multiple receivers and transmitters over a city area)

That's a programming issue. The timer is off by default and must be
enabled and set for a specific number of seconds. 60 seconds is the
typical timeout.

Digital radio comes in many flavors. One of the big advantages of
digital is that the repeater and channel can handle more than one
transmission at a time (either by TDM or FDM). Therefore a stuck
digital transmitter does not timeout or disable the repeater. In
addition, many such radios are full duplex, which allows the
dispatcher or comm shop to remotely disable the transmitter and yell
at the user. Whether the PSAP is setup and trained to do this is
debatable.

>Police used mobile transceivers in the cars on VHF and portables on UHF

Yep. Simply identifying the stuck transmitter is often insufficient.
I've heard stuck transmitters in vehicles rolling down the freeway for
an hour with a stuck transmitter. It was obvious who it was but

nothing short of an RF seeking missile was going to get their attention. In one case, someone noticed that they were listening to specific local radio station. The dispatcher called the radio station and had them make a special announcement to the driver to unstick the transmitter. It worked, instantly.

>Of course the equipment was aging by that time, it probably was from

>the operator to just tune out stuck transmitters or devices that fell
>into wrong hands.

Yep. Nice feature. In the US, the high end radios are P25. Various other narrow band solutions exist, most of which have remote programming and remote deactivation. Despite all the government programs intended to provide interoperability, the manufacturers (and the FCC) have gone out of their way to introduce proprietary enhancements and introduce intentional incompatibility.

Why I cannot get rid of that antenna I dunno,
all started because I could not get the PVC tubing which the many
internet sites propose. The plumber shops where I live can only supply
heavy massive material suited as killing weapon in the hands of a
desperate fox hunter.

So I had to look for an alternative design and that lead me
to the aluminium boom with the movable slider.

The most exciting discovery during the work was
that every boom has two ends.
You correct me if I am wrong.

Hmm, cue someone yelling "Yo mamma's so fat the antenna in her pants
is resonant on the 2200 metre band!"

I could see this antenna concept working for UHF and above.
Especially if they could make the other components "sewn in". i.e.
perhaps a hooded top or cap with Bluetooth headset embedded. More
likely such designs would be used to provide a level of shielding from
the wearer, so I suspect any such antenna would behave like a typical
patch antenna, with a radiation pattern being away from the body.

Even then though, it'd probably be a bit gimmicky.

This got a mention in the WIA news service a few weeks ago:

THE QNEWS WORK BENCH - the nuts and volts report -
(Measure twice - Cut once!)

BAE Systems tests T-shirt antennas

Wired reports that BAE Systems have teamed up with the UK's National
Physical
Laboratory to measure the efficiency of radiation emitted from
wearable
antennas embedded into T-shirts.

Wearable antennas could be a useful way of building communications
networks in
warzones or of monitoring and transmitting the health of the wearer.

Given that they are worn on the body, it is particularly important to
understand their performance. The human body absorbs electromagnetic
signals so
researchers were concerned that the signal could lose power if worn
too close.

Is this safe? I'm not allowed to exceed so many mW/meter at several
feet. I guess it depends how the current is distributed.

This concept has been around for at least 10 years, maybe more.

As you note, meeting the RF exposure limit is one of the challenges. However, spreading it out helps. the typical limit is somewhere around a few milliwatts/sq cm. So say you wanted to radiate 10 watts. If you can spread the antenna out over 0.1 square meter, then you're at 10mW/sq cm, and by the time you add some shielding and/or consider the duty cycle, you can stay below the limit.

(hey, better than putting an antenna 10cm long radiating 2 Watts next to your head, eh?)

Figuring out how to control the pattern is another.

One scheme (becoming more practical) is to make a phased array of sorts, with distributed switches throughout the fabric to turn segments on or off or change L/C loading.

Hams, at least in the US, tend to ignore all the rules about RF exposure (notwithstanding it's on the test, etc.). You see pictures of whip or

loop antennas clamped to picnic tables next to the operator or mag mount antennas stuck to the top of a "go box portable station" with a 100W rig.

yes, they're probably meeting the limit, once you take into account the duty cycle, etc., but I'll bet less than 0.1% of them have actually done the analysis to prove it. The typical response is "I've been doing this for years and I've never noticed any problem"

Not to mention that the safe harbor "assumed safe" limits only apply with "single transmitter".. and that's not just ham transmitters, so the cellphone on your belt qualifies as the second transmitter triggering the need to do the analysis.

So, I'm waiting for the QST article with the guy having a backpack SGC500 power cube driving their 20m wearable antenna.

****
-
My thoughts immediately were that with all the hype about cellphones causing
brain tumors, sterility, and perhaps herpes....that it is surprising that
anyone would be proposing wearable antennas.

However, these antennas have been around for a few years, in applications
such as "black" projects.

It will never take off for the general public for the simple reason that
what people wear is dictated by fashion, not cell phone reception.

The only place you will ever see such is in applications like military,
police, fire, etc. where having communications (other than cell) is part
of the job.

People in those situations are paid to take some amount of risk (sort of like working as a firefighter or nuclear worker)

If this is your opinion you can't evaluate hardware worth bleep.

The majority of what they sell does exactly what it's advertised to do.
You have to read the specs. And read the reviews carefully because
the hams who post that can't make the items work are often just ignorant
or incompetent.

It is not the best available, but it is often good enough.

You can call them up and complain directly to the designers. Try doing
that with Rohde and Scrwarz.

> You have to read the specs.

Generally true. However, I spent some time modeling the MFJ-1800
2.4GHz antenna and came the conclusion that it's not even close to 50
ohms and more like 300 ohms. I guess they forgot to include a balun:
<http://www.mfjenterprises.com/Product.php?productid=MFJ-1800>
<http://802.11junk.com/jeffl/antennas/mfj1800/index.html>
While one screwup is not sufficient to claim that the entire product
line is lacking, it does make me very suspicious and wary.

>And read the reviews carefully because
>the hams who post that can't make the items work are often just ignorant
>or incompetent.

True. Everyone that disagrees with me is automatically judged to be
incompetent, ignorant, or both.

MFJ-868 shows 21 reviews, most of them positive.
<http://www.eham.net/reviews/detail/6459>
The ones with critical reviews were either failures of some manner, or
what I attribute to calibration issues. Looking at the schematic at:
<http://www.mfjenterprises.com/pdffiles/MFJ-868.pdf>
methinks it's "good enough". I'm not thrilled by the design, but it
does have an integrating RC networks, with a 2 second time constant,
which would make it peak reading.

QST compares various wattmeters:
<http://www.palstar.com/qstWM150.pdf>
Unfortunately, the MJF-868 is not reviewed, but the article might
offer some clues as to what to look for in a wattmeter.

That's a pretty harsh statement there pal.I bought and used one of the
antenna tuners the proclaimed as "up to 300 watts" and the friggin'
4:1 balun blew out after 2 days of usage.I bought the contraption cuz
I didn't have the time or parts to build a really good one myself at
the time.
You really want a decent tuner do yourself a favor and take the time
and build one.Just google the K1JJ super tuner ,you'll thank yourself
and be a lot less lighter in the wallet for it.

I'm curious, did you do any measurement and testing with an analyzer, etc., or are all the figures simply calculated estimates?

Has anyone confirmed what the piece is that connects the driven element with the coax connector that looks to be a short piece of coax covered in heat shrink? Has anything been found or measured hiding under the heat shrink?

I realize we can all assume the antenna impedance is 50 ohms, but is it actually stated in any of the specifications from MFJ? I didn't see any mention of impedance specification at all for this antenna, but I could only find information on the web page at the link you provided as well as in the pdf file of the instructions for the MFJ-1800. The instructions are rather sparse.

Thanks for taking the time to provide details.

BTW, Irene's knocking at the door!

So that means every company that makes any product that has a problem
after two days is making junk? That's everyone BTW.

My second analyzer hasn't had a problem at all.

I've a 949 tuner - FB

I have a 993 auto tuner - never had a problem with it.

Now it is true that MFJ in general does not have the build quality of
some of the "better" units. It also doesn't cost anywhere near as much.
And their return policy is more generous than most.

And what to we get for this? I've put my analyzer up against some pretty
expensive units, and they all have similar problems with overload. And
given the price difference, I wouldn't be able to afford the more
expensive ones. So is it better to buy the "Mighty fine junk" or to do
without?

They actually perform a service to the amateur community. If you're too
good for MFJ don't buy their stuff. But you might have the grace to not
lord it over us lesser beings.

>I'm curious, did you do any measurement and testing with an analyzer, etc., or
>are all the figures simply calculated estimates?

There are no affordable "analyzers" that work at 2.4Ghz. I also have
not owned, or plan to own an MFJ-1800 antenna. The physical
measurements were done by a friend that owns this antenna and was
wondering why it didn't provide anywhere near the gain promised (as
compared to a commercial panel antenna).

Incidentally, I recently purchased a pair of totally misdesigned
2.4Ghz yagi's on eBay for about $8/ea.
<http://802.11junk.com/jeffl/crud/wi-fi-yagi-that-sucks.jpg>
Note the crude driven element, exposed coax conductors, and lack of a
balun. What happened was that this was a cheap clone of another
similar antenna, which did provide all the required matching
circuitry. This vendor decided it was too much trouble to copy the
matching network and balun, so he just left it out. It has more gain
to the sides of the yagi, than in front.

>Has anyone confirmed what the piece is that connects the driven element with the
>coax connector that looks to be a short piece of coax covered in heat shrink?
>Has anything been found or measured hiding under the heat shrink?

There's a ferrite bead under the shrink tube. If you can find a
ferrite material that actually works at 2.4GHz, it might pretend to do
something useful. However, no way is it going to provide a 4:1
impedance transformation.

>I realize we can all assume the antenna impedance is 50 ohms, but is it actually

Good point. One can assume that if it uses a 50 ohm coax pigtail, a
50 ohm N connector, and is designed to connect to a wireless device
that presents 50 ohms, it just might need to be a 50 ohm antenna.

>Thanks for taking the time to provide details.

Yeah, I've done dumber things. There were several long discussion on
the topic in various newsgroups. The discussions inspired my burning
several evenings modeling the antenna:

The Avago HSMS-2820 detector diodes in the MFJ-259 tend to blow up. It
apparently doesn't take much RF to do the damage. Suggest you buy
some spares from Digikey (516-1817-1-ND) or Mouser. Ten for about
$0.60/ea.

2102. Thoughts about the tape measure 3 element direction finding Yagi

Newsgroup: rec.radio.amateur.antenna
Date: 2011-08-28 20:09:00 UTC
From: "Helmut Wabnig"
Message-ID: <dn6l5759fk49bigjvgtv60t81aasng3qb0@4ax.com>
Source record: 3903

(repost updated)
All started because I could not get the PVC tubing which the many
internet sites propose. The plumber shops where I live can only supply
heavy massive material suited as killing weapon in the hands of a
desperate fox transmitter hunter.

So I had to look for an alternative design and that lead me
to the aluminium boom with the movable slider.

With the PVC tubes it should be possible to make the middle "T"
moveable, or not? Would have to drill through the T with
a larger diameter wood-drill.
http://tinyurl.com/3vygo9f

I am here now:
https://sites.google.com/site/tapemeasureantenna/
This allows for future changes, updates and additions.

The old stuff is still there:
http://img839.imageshack.us/img839/1452/tapemeasurefoxhuntyagi.pdf

What's missing is a list of ready-to-build recipes.
Am still struggling with the tape-measure correction factors
for the antenna simulator (4nec2)
Anybody having already tried simulating tape measure antennas?

3 element Tape measure direction finding antennas are a bit larger
than their 2 element competitors like the MAY1000
http://www.rfparts.com/diamond/MAY1000.html
A simple two element ARDF antenna must be carefully adjusted
in element spacing, else it will be totally worthless. This often
applies to the portable HB9CV antennas from the junk box
which are being used off their design frequency.
I cannot imagine running through underbrush thicket with the MAY1000.
It will quickly fold into it's sales package size :-)

w.

Regards,
w.

Not tape measures, but I have done stamped sheet metal, which is
somewhat similar. See the plots at:
<http://802.11junk.com/jeffl/antennas/mfj1800/index.html>
The NEC2 deck is under:
<http://802.11junk.com/jeffl/antennas/mfj1800/slides/mfj-1800.html>

The problem is that the common "wire" rod antenna elements aren't
close enough. So, I had to use the actual dimensions from the sheet
metal. You'll probably need to do the same, with the added
complication of including the arc in the cross section. It's not as
horrible as it might seem as all your elements are the same cross
section. Use the "Geometry Builder" program that comes with 4NEC2.

>I cannot imagine running through underbrush thicket with the MAY1000.
>It will quickly fold into it's sales package size :-)

Have you considered an inflatable version?

<http://www.scouting.org/filestore/jota/pdf/TURNER.pdf>
Hmmm.... they use a WB2HOL tape measure antenna.

They don't blow up, they burn up. Always keep the input grounded (I have a banana plug ground I use when storing my 259B) until you are ready to use it. Short the center conductor of the DUT to ground immediately before connecting to the 259B. Do not transmit from any nearby antennas.

A tin can is too small. I think you mean a coffee can.
In my never humble opinion, the cantenna sucks, but works tolerably
well for illuminating a parabolic dish.

Here's a model of the common coffee can antenna.
<http://802.11junk.com/jeffl/antennas/coffee2400/>
Notice the boresight error caused by the off center probe feed. 9.8dBi
gain, but there's a problem with my model somewhere. The average gain
test shows 1.54 indicating that the calculated gain is 1.88dB too
optimistic. The real gain is more like 8dBi. I can do that with a
biquad.

The cantenna also has a problem with calculating the probe feed
length. Where do you measure to? Starting from the tip, do you
measure to where the insulation stops on the N connector? To the
metal sleeve around the insulation? To the N connector base? Or
perhaps to the tin can itself? The error is not trivial. 1/4 wave at
the band edges are 3.02cm and 3.12cm. Assuming you want to land
somewhere between these limits, the cut error is:
3.12cm - 3.02cm = 0.10cm = +/-0.5mm
That's also possibly one of the reasons the original designer used a
conical probe feed. More bandwidth means any error has a smaller
effect.

I won't mention that the bottom of the can is rarely flat, making that
distance also a bit tricky to get right. Never mind that there's way
to adjust anything other than the length of the wire probe and it's
bend angle.

About 3 years ago, I was blessed with a friend who built about 6
assorted cantennas, but had no reliable way to tune or test them. I
stupidly volunteered. Most of them were resonant at about 1.8GHz.
Chop, cut, hack, solder, and they're now on 2.4Ghz. Measuring the
gain, none of them came close to what was expected. My indoor antenna
test range leaves much to be desired, but my transfer standard antenna
is accurate to +/-0.5dB gain.

The reason that the cantenna is such a "killer" antenna is that
literally *ANY* external antenna is an improvement over the stock
chip, PIFA, or rubber ducky collinear antenna found in most Wi-Fi
contrivances. You can even build one incorrectly and it will work

better than the stock antenna. For your amusement, here's a proper
biquad:
<http://802.11junk.com/jeffl/antennas/Biquad/index.html>
and by the way far too many web pages suggest it should be built:
<http://802.11junk.com/jeffl/antennas/biquad-junk/index.html>
The good antenna has a 50 ohm coax feed between the reflector and the
bow tie. The loser has a pair of wires, at some unknown impedance, in
the same place. Amazingly, it has almost the same gain, despite the
high VSWR.

Killer antenna, my posterior...

Incidentally, I once scribbled a spreadsheet that allegedly generates
an NEC2 card for a cantenna, given the can dimensions.
<http://802.11junk.com/jeffl/rf-calc/Coffee-can05.xls>
In theory, you should be able to cut-n-paste the section in blue, save
it as filename.nec, and feed it to 4NEC2 as can feed. It was
originally intended for parabolic dish feeds, but can be used for a
stand alone wi-fi antenna. Unfortunately, it's not ready for prime
time and has some errors. It's been so long since I threw it
together, that I don't even remember what was broken. Caveat Emptor.

Nope. That's on how to build a cantenna. What I'm doing is taking a given size can, and generating an NEC2 deck suitable for modeling the design. There's nothing on that web page about modeling. For that matter, there are no test results and no cool looking plots. You could build the cantenna according to the instructions, and never really know what you've got, or what to expect.

Incidentally, I like the various photos of testing the cantenna on a camera tripod. My guess is that the tripod is about 3ft off the ground. Quiz: What's the maximum distance you can go at 2.4Ghz with both ends 4ft off the ground, before the Fresnel Zone hits the ground?
<http://www.terabeam.com/support/calculations/fresnel-zone.php>
Plugging in various guess in the range, I get 0.025 miles or 132 ft.
Several of the antenna tests (can't find the link again) were longer.
Oh well.

Good tip, Jeff. One thing that would be cheap insurance and make for less units shipped back is a dummy load to put on the antenna socket. I made one up for cheap.

>Perhaps some of your modeling suggests this.

The model is at:
<http://802.11junk.com/jeffl/antennas/coffee2400/index.html>
Note the 5 degree boresight error at:
<http://802.11junk.com/jeffl/antennas/coffee2400/slides/horiz-01.html>
That's not too horrible considering the 65 degree -3dB beamwidth.

I've seen several antenna with proper launchers. Here's one:
<http://www.seattlewireless.net/CookieCantenna>
The funnel will add about 4-5dB of gain depending on size. That begs
the question whether it would be easier to just built a horn antenna
and be done with it. The horn has more gain, easier to build, flat
surface for easier connector mounting, tunable back end of waveguide,
and potentially more portable:
<http://www.wired.com/culture/lifestyle/multimedia/2004/08/64440>
<http://www.brest-wireless.net/gallery/AntenneCornet>
<http://www.seattlewireless.net/CardboardHorn>

Also, I forgot to mumble something about the N connector mounting
screws and nuts projecting into the waveguide. Not a good idea as
those will have some effect. The screw heads should be on the inside
of the can, with the nuts and uncut threads on the outside. It will
look horrible but it will work better. Copper pop-rivets would
probably be best.

I have a 2.4 GHz TV downconverter built into a coffee can. It was
tough to get a good picture, so I made a horn for it, using hardware
cloth. The horn is about three feet long and about three feet across
at the open end. I never made any quantitative measurements of the
increased signal at Channel 3 (the nominal output) but the reduction
in snow was considerable.

Hi. I foxhunt regularly with the Melbourne ARDF community,
and we have the design of 2m sniffer antennas down to a fine art.

The best material for the shaft is 12mm square or u-channel aluminium.

The common antenna element length and spacing recommended with the
tape-measure antenna is wrong - very wrong. For a start, the lengths
vary by too much (in the hope of a wider effective bandwidth), and
the reflector is too close to the driven, the director too far away.
This causes large rear side lobes, which makes sniffing incredibly
frustrating.

For effective sniffing, you *don't* want maximum F/B ratio, and you
don't want maximum gain - what you want is a cardioid pattern with
just one lobe - the front one. Anything else will give you a bum
steer.

The best pattern we've found so far is the VK3VT beam:
<http://www.vk3vt.net/VTbeam.html>. Most of the recent ones use a
gamma match instead of the one shown.

We build this using elements made up from 3mm fiberglass rod and
co-ax braid, covered by heatshrink. The element goes through a
short copper tube before the heatshrink goes on.

These elements are sufficiently stiff to keep their shape, but
whippy enough to run with through a tree.

Clifford Heath.

I just ground the center of the SO-239 with a common Pomona banana plug.
A 50 Ohm load isn't necessary.

> - 73 de Mike N3LI -

Dummy load or short, it doesn't matter. It's probably not RF that's
killing the diodes.

Schematic of the MFJ-259B at:
<http://www.dk3red.homepage.t-online.de/en/s8a.htm>
I took the liberty of somewhat cleaning up the RF input section at:
<http://802.11junk.com/jeffl/crud/MFJ-259B-RF-section.jpg>
Note that diodes D2 and D3 are directly connected to the center pin of
the RF connector. These are the two that usually blow up, not the
others. Oddly, I'm finding both blown, never a single diode. My
guess(tm) is that they're being killed by a blast of static
electricity, not RF.

Notice the lack of a high value bleeder resistor on the antenna
connector. This bleeder resistor is standard on anything connected to
an antenna that might build up a static charge. Every radio that I
designed has this resitor. It doesn't take much static electricity to
blow an unprotected diode. Just connect the MFJ-259b to an ungrounded
antenna in a wind on a low humidity day, or just touching the antenna
while sliding across a plastic car seat. When I replace the diodes,
I've been adding a 100Kohm resistor from the junction of D2/D3 to
ground, which hopefully will help. So far, no returns.

> compared to a commercial panel antenna).

Hmmm.. while you might not be able to buy an analyzer, that doesn't mean that you couldn't have done the measurement by other means. A power meter (perhaps an eval board for one of the analog devices parts)? Maybe even using a WiFi card as a field strength meter at a little distance away, and then using an adjustable stub tuner (e.g. microstripline on a PC board. (or one of those "check your microwave oven for leakage" meters from radio shack)

Sure, it's not as nice as that VNA from Anritsu or Agilent, but people have been making microwave impedance measurements for decades with pretty primitive gear.

Building a directional coupler in microstripline is a cookbook endeavor. An hour with some copper clad board and a razor blade would do. If you happen to have some copper foil tape around, it's even easier.

An impedance measuring system along the lines of the "3 meter" technique (where you have a known L or C in series) is a possibility.

Not to mention that there are a lot of folks on this list who DO have
access to suitable analyzers.

So Renee's question was pretty reasonable.

Fascinating... especially since the matching network wouldn't normally
have any effect on the pattern. Balun/Choke having an effect, I could
see (coupling to the feedline screws up the pattern).

2.4 GHz is 12 cm wavelength

4-6cm of transmission line is a good fraction of a wavelength. How do
you know it's not 3/4 lambda of 75 or 92 ohm line, or something like
that. (1/4 wavelength of 75 ohms would transform 200 ohms to about 30
ohms, for instance)

I've worked with enough UHF and microwave antennas with weird funky
feedpoint things to not trust in first impressions. There could be all
sorts of parasitics that help the situation out, and they're tough to
model accurately (you're certainly not going to do it with NEC, for
instance.. I'd trust NEC for the feedpoint impedance without
matching/balun/stubs..)

Yeah, it's probably not a nice 1:1 match over the entire band, but then,
most antennas aren't. It just has to be "good enough" and in that
business, the loss in the feedline probably dominates anyway. Figure 3
dB of loss in the feedline, and you get a 6B improvement in return loss.

The model you have shows a beamwidth around 30 degrees (H) and 28
degrees (V).. that's a directivity around 16 dBi

4NEC2 is giving you 14dB gain.. that's moderately consistent, although 2
dB is something I'd want to figure why the difference. I'd want to

figure out why 2dB different, especially since you didn't put resistive
loading into your model, which, at 2.4GHz *will* make the match better

MFJ claims 15dBi, and that is also consistent with your model and the
back of the envelope from the pattern.

> 50 ohm N connector, and is designed to connect to a wireless device
> that presents 50 ohms, it just might need to be a 50 ohm antenna.

Nope.. not if the feedline is a couple dB loss (which wouldn't be
unusual for a laptop pigtail using RG-174 or smaller).. All they really
care about in this kind of application is the directivity.

After all, how many ham antennas for HF have a PL-259/SO-239 "UHF"
connector on them. I wouldn't take the fact that it has a 50 ohm
connector as indicating anything other than it's a common connector that
people are likely to have mating connectors for.

75 ohm BNC, Ns, etc exist, but how many people use them on dipoles
(which have 72 ohm impedance)... nahh. they just use a 50 ohm cable, UHF
connectors, and are done with it.

If they used 75 ohm coax on this antenna, and it's close to a multiple
of 1/4 wavelength, then the match at the N connector is probably not a
lot worse than using 50 ohm coax on a dipole.

Well, not having the antenna prevented me from doing much. If I had
the antenna, I would have connected it to a home made reflection
coefficient bridge and my Wiltron 610D sweeper. I also have some
directional couplers, but all my detectors are currently blown.
<http://802.11junk.com/jeffl/pics/home/slides/BL-shop6.html>
(Right now, there's a chain saw torn apart on the bench). Either
bridge or coupler would have shown high VSWR for the antenna.

Incidentally, I don't consider it my job to supply test data for MFJ.
MFJ should run the tests and post both the procedures and test
results.

While it's a good thing to verify models with actual measurements, in
this case, just creating the model burned all my spare time for about
a week. I don't think I would have had time to do anything more than
a rough sanity check type of test.

>A power
>meter (perhaps an eval board for one of the analog devices parts)?

I have several microwave oven testers. They will barely detect RF
from an access point. Basically, they're just a diode detector, with
no RF gain. I wouldn't expect much from them:
<http://802.11junk.com/jeffl/pics/Microwave%20Leakage%20Detector/>
The detector diode is on the far left.

I do have an indoor antenna range of sorts. It's full of reflections,
but is good enough for measuring gain using a reference antenna. In
this case, I had a patch antenna and a biquad antenna tested in an
anechoic chamber and obtained fairly accurate gain curves. My guess
is that I can measure gain at 2.4Ghz to +/-2dB. Not great, but better
than guesswork.

>Sure, it's not as nice as that VNA from Anritsu or Agilent, but people

I still have several slotted lines buried somewhere.

>Building a directional coupler in microstripline is a cookbook endeavor.
> An hour with some copper clad board and a razor blade would do. If
>you happen to have some copper foil tape around, it's even easier.

Yep, I've done that. On a good day, I'll get 20dB directivity, which
isn't so great.
<http://www.qsl.net/n9zia/24swr/index.html>
I prefer a reflection coefficient bridge, as in:
<http://pe2er.nl/wifiswr/>
I've built several of these. It won't tell you whether the antenna is
inductive or cazapitive, but will supply the VSWR (actually, the
reflection coefficient).

>An impedance measuring system along the lines of the "3 meter" technique
>(where you have a known L or C in series) is a possibility.

Pardon my ignorance, but what's that?

>Not to mention that there are a lot of folks on this list who DO have
>access to suitable analyzers.

Great. Let them borrow and MFJ-1800 antenna and run their own tests.
>So Renee's question was pretty reasonable.

True. I should have tested my model to verify my allegations. Perhaps
I should also do indoor/outdoor tests, in various environmental
situations, in the presence of interference, and with a side by side
comparison with other antennas. Yeah, that would be great, but I
don't have that much time (or money). I threw together an NEC2 model
that suggested that the antenna is mis-designed and left it there.

>> Incidentally, I recently purchased a pair of totally misdesigned

I didn't include the feedline in my model, which due to the lack of a
balun (I don't consider the ferrite bead to be a balun due to the high
frequency) will radiate and produce weird patterns. Never mind the
fairly large lengths of exposed conductors at both ends of the coax
cable. I'm not sure exactly what a 200 ohm antenna in a 50 ohm system
will do. 300 ohms in a 50 ohm system is a 6:1 VSWR and a 3.1 dB
mismatch loss. So what if we loose half the power in the mismatch.

The owner of the antenna measured the coax cable dimensions. From
that, we determined that it was 50 ohms coax. I have the numbers
buried in email correspondence somewhere. I'll see if I can find
them. Digging.... Nothing yet, but I did find one more photo:
<http://802.11junk.com/jeffl/MFJ-1800/>
While it's difficult to transfer dimensions from the photos, the coax
cable even looks like a 50 ohm cable. Not the thick center conductor,
which makes 92 ohms improbable, and 75 ohms unlikely. You can see the
ferrite beads through the stink tube.

>I've worked with enough UHF and microwave antennas with weird funky

Well, that's what my model did. The characteristic impedance of the
model is set to 200 ohms at the folded dipole. No matching network
involved. See:
<http://802.11junk.com/jeffl/antennas/mfj1800/slides/VSWR.html>
and note the 200 ohms in the upper left of the VSWR graph.

>Yeah, it's probably not a nice 1:1 match over the entire band, but then,
>most antennas aren't.

Look again at the graphs.
<http://802.11junk.com/jeffl/antennas/mfj1800/slides/VSWR.html>
It's absolutely gorgeous across the band. Less than 1.3:1 from 2400
to 2483.5. I would also have expected a much more narrow band antenna
and was very surprised at the wide bandwidth. That's not normal for a
high gain yagi.

>It just has to be "good enough" and in that
>business, the loss in the feedline probably dominates anyway. Figure 3
>dB of loss in the feedline, and you get a 6B improvement in return loss.

Yep. That's why I measure VSWR at the antenna, not the source. I
like to use LMR-400 with 6.6dB loss per 100ft. 3dB loss would be
about 50 ft of coax cable, which is MUCH longer than I would use at
2.4GHz. Also, I'm partial to putting the radio next to the antenna,
which reduces coax losses to nearly zero.

>The model you have shows a beamwidth around 30 degrees (H) and 28
>degrees (V).. that's a directivity around 16 dBi

Yep. For the benefit of those trying to follow all this, see the
numbers in red at the right:
<http://802.11junk.com/jeffl/antennas/mfj1800/slides/Horiz.html>
Incidentally, notice the asymmetrical pattern, caused by the off
center line position of the copper folded dipole driven element.

>4NEC2 is giving you 14dB gain.. that's moderately consistent, although 2
>dB is something I'd want to figure why the difference.

The 2dB is from the -2dB gain in the reverse direction (180 deg).
14dB forward gain. -2dB reverse gain. 14 - (-2) = 16dB directivity.
I don't see a problem.

>I'd want to
>figure out why 2dB different, especially since you didn't put resistive
>loading into your model, which, at 2.4GHz *will* make the match better

Ummm... why would I need a load? I'm only interested in what the
antenna looks like to whatever I connect to the terminals. If I
included the generator source impedance in the model, I would have to
also include the generator output impedance characteristics,
connecting cables, and possibly some manner of 4:1 xformer.

>MFJ claims 15dBi, and that is also consistent with your model and the
>back of the envelope from the pattern.

Close enough. When in doubt, always round up to make the numbers look
better.

Maybe. Using coax loss to improve VSWR is an old trick. Whether it's
being done intentionally is debatable. I prefer to assume that if all
the major components are 50 ohms, then perhaps the antenna should also
be 50 ohms.

>After all, how many ham antennas for HF have a PL-259/SO-239 "UHF"
>connector on them.

Too many. However, HF antennas are not as critical to construction
and component differences as microwave antennas. What hams get away
with building HF antennas, would be doom and disaster at microwave
frequencies. You also don't see UHF connectors and banana jacks at
UHF frequencies.

>I wouldn't take the fact that it has a 50 ohm
>connector as indicating anything other than it's a common connector that
>people are likely to have mating connectors for.

Ok, I'll conceded that there's a possibility that there's some
matching magic going on behind the curtains, that's not visible to
mere mortals. Lacking the necessary insight, I prefer to judge based
on what I can see, feel, touch, understand, and test.

>75 ohm BNC, Ns, etc exist, but how many people use them on dipoles
>(which have 72 ohm impedance)... nahh. they just use a 50 ohm cable, UHF
>connectors, and are done with it.

Most of the feed lines to my roof are 75 ohm CATV rigid cable. Also,
plenty of 75 ohm RG-6a/u. Worst case VSWR for doing this is 1.5:1.
The tiny mismatch loss for this arrangement is more than compensated
for the lower coax loss of 75 ohm coax, compared to similar sized 50
ohm coax.
<http://www.qsl.net/n9zia/wireless/75_ohm_hardline.html>

>If they used 75 ohm coax on this antenna, and it's close to a multiple
>of 1/4 wavelength, then the match at the N connector is probably not a
>lot worse than using 50 ohm coax on a dipole.

The antenna impedance (by my model) is between 200-300 ohms. To use a
1/4 wave section to match that to 50 ohms, the coax would need to be:
Zo = (Zout * Zin)^0.5
Zo = (200 * 50)^0.5 = 100 ohms
93 ohm RG-62/u would probably be close enough. However, the coax
cable in the photo is certainly not 93 ohms (judging by the fat center
conductor).

Did you exceed the ratings of the device?

Silly question, because you probably didn't know the load you were
trying to match.

You wouldn't be the first person to damage a '300W ATU' witha transmitter of less than 300W.

The point is that the power ratings on ATUs (and lots of other accessories, eg baluns) are extravagant giving that they are not explicitly conditioned on some operating parameters.

I expect that an MFJ949E will handle 300W from 160m to 10m if matched into a 50 ohm load... but does that make such a statement a worthwhile specification for the thing. No, of course not because if you had 50 ohm load you don't need the ATU.

Do the specifications for this or any ATU state X kW at any load impedance (any magnitude, any phase)... not in my experience.

I have heard people brag that "my ATU is so good, I can get VSWR=1 with not antenna attached". Ok, that is a recipe for damaging the ATU, and if it was an MFJ949E and its voltage balun was in circuit, that would be at risk.

I wrote some notes at http://www.vk1od.net/transmissionline/aev/index.htm about high voltage damage to ATUs, and realise that not only may it cause flashovers, but high voltage causes highest dissipation in voltage baluns.

Owen

Do you think the matching affects the cardioid or F/B pattern?
So far I have neglected any influence from that.

With the YAGICAD optimizer I could not come to a positive end.
This program finds 100 different "optimums" therefore
I turned to 4nec2 now.
The patterns which YAGICAD calculates look good to me.
When I compare the F/B patterns, of course the 4nec2 has a more
detailed "resolution" showing minor side lobes where YAGICAD

is just approximating.

I wonder how important matching is for a pure
direction finding antenna, methinks rather it should not.
Only the coax cable currents are not considered
in the simulator diagrams, there might be an influence.
Therefore matching is important :-)

Thank you for the vk3vt link.

I was looking at cheap HT's last night on eBay and I found several vendors selling duplexers for repeater use. They sell for about $60 each.

They are 6 cavity (three transmit, three receive) and the closest they can go on VHF is 3.5mHz.

Doing a web search I find they are not very good (what did you expect?) but with a good front end they will work ok.

My problem is not only one of money (don't tell me to not waste my money and buy a good, one, I can't afford it), but my 2m band is only 144-146 mHz, and the repeater portion is really just 145-146. I'm also limited to 20w output.

So my question is anyone familar with them? Is it possible to take one and convert it to a 6 cavity input filter? For example, I could put the input on one side my yard and the output on the other, about 30 feet apart.

For example, if the input of the repeater was 145.600, could I have them both tuned to 145.600 and connect the input of the receiver to one set of cavities, the antenna to the other and leave the antenna connection untouched, effectively placing them in series?

Thanks in advance,

Geoff.

No. There are two sides, one of them for the high frequency and the
other for the low frequency. The filter response is such that it passes
on one frequency and notches on the other.

Ok thanks. Note that they are tunable anywhere in the 136-17? range.

Assuming the pass side is set to pass 145.600 (the input) and the notch side is set to notch out 145.000 (the output) and they are connected in series, would that work?

It is not a pass side and a notch side. Both sides are pass/notch.

But on one side the pass freq is above the notch freq, and on the
other side the pass freq is below the notch freq.

On the Chinese duplexers you have found, the Q is probably not high
enough to tune the pass and notch to frequencies 600 kHz apart.

We still don't have a clear description of what the OP is trying to
accomplish.

He is wondering if something can be modified. He wants a half-duplex
radio with a 600 kHz split, on a common antenna. The duplexer he is
looking at has a 5 MHz offset. He wants to know if it can be
re-configured for ham with a much smaller offset.

Take two radios, two j-poles and a lot of coax and make a repeater.
Obviously I will need some sort of controller in between but that's
irrelevant.

I want to place one J-pole (or similar antenna) at one corner of my garden,
and another at the other one (10 meters apart).

One will be used to receive a signal, the other to relay it. They both
will be somewhere on the 144-146mHz band, with the output being a few watts
with a max of 20.

Besides the distance, I was looking for a cheap way of not having
the transmitted signal block the receiver. The duplexer in question
is rated at 75dB isolation with a 3.5mHz split, I can only have .6 mHz.

What I was wondering is that since at a .6mHz split, the isolation will
be a lot less, can I somehow combine the two sides to make a better
filter?

Thanks,

Geoff.

There are calculators that will predict the isolation. At 20 watts
(+43dBm), with a broadband synthesizer noise level at about -30dBm,
and an RX sensitivity of about -106dBm, you'll need at least 76dB of
TX-RX isolation. The little cavities have too wide a notch (i.e. low
Q) and will attentuate the RX signal and smoke the TX signal at 0.6Mhz
spacing. Seperating the antennas won't solve that problem. If you
try to get sufficient isolation using vertically isolated antennas,
you might get sufficient isolation, but the Q of the notch filters
will still kill the signal both ways.

Vertical antenna isolation:
<http://awapps.commscope.com/products/bsa/_calculators/qvisolation.asp>
Horizontal antenna isolation:
<http://awapps.commscope.com/products/bsa/_calculators/qhisolation.asp>

>For example, if the input of the repeater was 145.600, could I have them
>both tuned to 145.600 and connect the input of the receiver to one
>set of cavities, the antenna to the other and leave the antenna connection
>untouched, effectively placing them in series?

Nope. Not enough Q (too wide a notch).
Bigger cavities = higher Q.
More cavities = deeper notch and therefore more isolation.

Quiz: The Q of given cavity is 1000. If I critically couple 2 such
cavities in series, what is the resultant Q? 10 such cavities? etc?

Answer: 1000 in all cases. The 3dB bandwidth does not change when
tuned circuits are critically coupled.

Read the specs on the eBay web page. For example:
<http://www.ebay.com/itm/110460354111>
"Minimum Tx and Rx frequency difference: VHF 3.5Mhz"
That's not going to work with 0.6MHz spacing on the 2m ham band.

This is what a proper (Phelps-Dodge) 2m duplexer looks like:
<http://www.LearnByDestroying.com/k6bj/K6BJ%20Repeater/slides/2m%20duplexer2.html>
Note the much large size cavities.

>and another at the other one (10 meters apart).

Plugging into:
<http://awapps.commscope.com/products/bsa/_calculators/qhisolation.asp>
I get about 30dB isolation (assuming 2dBi antenna gains).
The synthesizer noise belching from your xmitter is maybe -60dB down
from the +43dBm xmit carrier. That puts the noise level at -17dBm at
the receive antenna. Your receiver sensitivity is probably -106dBm,
which means you need about 90dB of isolation. The antenna spacing
will provide 30dB of that. You cavities are suppose to provide the
remaining 60dB of isolation. That's not going to happen with tiny
mobile duplexer cavities.

Hint1: You'll be close with vertical antenna isolation.
Hint2: Some radios have quite a bit of synthesizer noise, much of
which will be on your repeater receive frequency. This is why some
repeaters still use crystal oscillators instead of synthesizers.

>One will be used to receive a signal, the other to relay it. They both
>will be somewhere on the 144-146mHz band, with the output being a few watts

Somewhere? Duplexers are usually bench tuned to some specific
frequency. It's not a trivial exercise and requires some expenditures
in time and equipment. You can't easily move in frequency.

>Besides the distance, I was looking for a cheap way of not having

>filter?

You can't improve things by simply adding more cavities. All you'll
do is add more loss:
Bigger cavities = higher Q and therefore closer frequency spacing.
More cavities = deeper notch and therefore more isolation.

You should have stopped writing at the first thought. CHOKING is
supremely important, and is a benefit found in good matching design.
Choking can be achieved without matching, however. And choking will
be needed at least at the feed point, and again a quarterwave down the
line.

Why? Don't you make experimental stuff? I did not say it was a permanent
repeater, it's actually a test bed for some repeater/internet linking
systems we are trying out.

Budget is zero, but I can swing a roll of rg-6 and maybe a $60 duplexer
if I don't buy anything else (radio/computer related) that month.

OK, thanks.

Explain, do you mean just the distance if they are both vertical, or
the distance AND one is vertical and the other horizontal?

> Hint2: Some radios have quite a bit of synthesizer noise, much of

Also almost irrelevant. The radios wll be what I have, HTX-202s or what
I can scrounge (TBD). I'd love to get my hands on 2 channel Maxtracs
or similar radios out of taxis, but the people sitting on piles of them are
much more interesting in refurbishing and enhancing them than selling them
cheaply or giving them away.

I'd be very happy with ones that receive only or have blown finals that I
can get 2w or so out of.

I know, but I don't have a "pair" yet. I'm not even sure there are any
available or a test one. So why be specific when I don't have that information
yet, and why wait for it to ask a technical question, which will have
the same answer no matter which frequencies I use?

> You can't improve things by simply adding more cavities. All you'll

one might be able to cascade two of them, but Rob's point about Q is
well taken.

It depends on whether the problem is the "depth of rejection" or the
"steepness of skirt". A single resonant unit has a narrow spike on top
of gentle shoulders. Say one section has Q of 1000 (i.e. the 3dB
bandwidth is 100kHz for 100MHz center frequency), but the rejection at 1
MHz away is only 20dB. I could cascade 3 sections, tuned exactly the
same, and I'd have 9dB loss at 100kHz, and 60dB rejection at 1 MHz away.
The 3dB bandwidth might be around 30kHz, or, you could stagger the
tuning slightly to get a little broader flat top, but keep the 60dB
(i.e. moving the center frequency of one cavity by 10kHz won't change
the attenuation at 101 MHz)

The design challenge is that you need to suppress the transmit signal
(at, say, 50W, +47dBm) low enough so that the front end of the receiver
can handle it without blocking (say, you want it down around -50dBm).
With our not so hot cavities described above, you'd need to stack up 5
sections at 20dB per section to get the 100dB suppression. Well, that's
not so great, because you probably now have a bunch of additional loss
in the receive path, AND you've got a real tuning chore on your hands to
make sure that all of them are tuned appropriately to get the required
bandwidth.

Enter the idea of a notch. Let's say our example is 101 MHz Tx and 100 MHz Rx. Rather than rely on the "far away" response of a resonator to suppress the transmit, I can put a 101 MHz notch filter on the input to my receiver. If I can get 30dB/section rejection, then 3 or 4 sections will knock the Tx power down low enough to not block the receiver's front end.

But wait, there's more... that Tx isn't a narrow spike. It has phase noise sidebands that go out fairly far. Unfortunately, the run of the mill transmitter might only suppress "off channel spurious and noise" by, say, -50dBc (and a rig designed to operate half duplex is probably worse). That means that your 50W (+47dBm) transmitter is putting out -3dBm *at the receive frequency*, so no amount of filtering on the receive path will help. Again, enter the notch filter.. you put a 100 MHz notch on the output of the transmitter.

Now.. as Rob points out, the Q might be kind of low. If the Q is, say, 100, then that 100MHz filter is 1MHz wide, and by the time you cascade enough to get the BW down, the loss will be huge.

As you can see, this whole duplexer/diplexer/multicoupler design thing can get pretty complex, and there's not usually a simple cookbook answer.

> and another at the other one (10 meters apart).

This will actually help a bit

The free space attenuation for 10 meters at 144MHz is
32.4+20*log10(0.01)+20*log10(144) 32.4-40 +43.2 = about 36dB.

If your Tx is 20W (+33dBm), then the receiver is going to see about
-3dBm at the Tx frequency. If you want to get the Tx signal down to
around -40dBm or so, you only need 30-40 dB of attenuation at the Tx freq

Then there's the Tx phase noise to worry about. Figure it's 60dB down,
so +33-60-36 = about -63dBm.. probably enough to completely mask any
received signals (what's your sensitivity.. -130dBM?) so you need a
notch with 70dB rejection on the output of your Tx.

You're 600kHz away, implying you need a Q better than a few hundred.
If you just tune up some of those cans for that, and the Q is too low,
then you'll be attenuating your transmitter.

Any reason why you're using a split of 600kHz? Why not go to a
non-standard split to make life easier. Pick two frequencies 3 MHz apart
(assuming you can get them coordinated, which is more a political than a
technical issue)

>Why? Don't you make experimental stuff?

I don't like J-pole antennas. I've also built too many repeaters in
the past to know that they can't just be thrown together from
available parts. One of my friends learned that expensive lesson with
his 2m repeater. He started with two ham transceivers, went to two
Maxtrac radios, and finally to a GE MSTR II. Duplexers went from 4
cavity junk, to a 6 cavity monster.

>I did not say it was a permanent
>repeater, it's actually a test bed for some repeater/internet linking
>systems we are trying out.

Sounds interesting. Plan on everything costing at least 4 times
what's predicted, and for things to take perhaps 4 times as long.
Unplanned repairs and "tweaks" should double the required time.

>Budget is zero, but I can swing a roll of rg-6 and maybe a $60 duplexer
>if I don't buy anything else (radio/computer related) that month.

Initial budget can be zero. Just plan on a replacement budget equal
to the price of a proper repeater.

How's this for an expensive mistake?
<http://802.11junk.com/jeffl/K6BJ-MSF5000/>
I've burned about $800 on this mess and it's still not on the air.
Wanna guess what went wrong? (Hint: it involves the internal
duplexer).

>><http://awapps.commscope.com/products/bsa/_calculators/qhisolation.asp>

>> Hint1: You'll be close with vertical antenna isolation.
>
>Explain, do you mean just the distance if they are both vertical, or
>the distance AND one is vertical and the other horizontal?

Assuming vertically polarized monopole antennas, vertical isolation is
from tip of one antenna to the tip of the other antenna. Horizontal
isolation is just the horizontal spacing. If they're seperated both
vertically and horizontally, then there's a problem. You only need to

be offset horizontally slightly, for the antennas to couple. I ran
into this problem when I tried to put two vertically seperated
antennas on opposite sides of a tower. The isolation was better then
they were directly in line with each other, on the same side of the
tower. Incidentally, mounting one antenna upside down offers
additional distance and improved isolation.

>> Hint2: Some radios have quite a bit of synthesizer noise, much of

>
>Also almost irrelevant. The radios wll be what I have, HTX-202s or what
>I can scrounge (TBD).

Retch 2.0. Radio Shock HTX-202 handhelds tend to stick on the air
with low battery voltage. The receivers are also easily overloaded.
We have the remaining few HTX-202 radios used for APRS WX packet. I
would love to replace them, but nobody (including me) want's to spend
the time.

>I'd love to get my hands on 2 channel Maxtracs
>or similar radios out of taxis, but the people sitting on piles of them are
>much more interesting in refurbishing and enhancing them than selling them
>cheaply or giving them away.

Patience. On Jan 1, 2013, everything in the US is suppose to go
narrow band. There should be tons of cheap radios available on eBay
and from public safety outlets.

>I'd be very happy with ones that receive only or have blown finals that I
>can get 2w or so out of.

Make sure you get the ones with the 16 pin accessory connector. Many
of the Maxtrac's on eBay are actually cobbled together Radius or M120
radios, with odd boards and strange firmware. Caveat emptor.

>I know, but I don't have a "pair" yet. I'm not even sure there are any
>available or a test one. So why be specific when I don't have that information
>yet, and why wait for it to ask a technical question, which will have
>the same answer no matter which frequencies I use?

Careful. Some repeater frequencies are a problem. For example,
146.760 is on the 41st harmonic of the common 3.579545MHz clock osc
frequency. No problem at the repeater, but it will drive the users
nuts.

If co-located with other radios, be sure to do an intermodulation
study.
<http://www3.telus.net/PassiveRF/>
We found out too late that a mix of some of our transmit frequencies
lands on one of our inputs.

>> You can't improve things by simply adding more cavities. All you'll
>> do is add more loss:
>> Bigger cavities = higher Q and therefore closer frequency spacing.
>> More cavities = deeper notch and therefore more isolation.
>
>And that's the answer I need.

You might find it easier to build a UHF repeater. With 5MHz spacing,
the cheap mobile duplexers will work with low power (<25w) radios.

> results.

Why should they bother. They have someone do a design that seems to work acceptably well, and they sell it at a bargain price. You want published test data and test procedures and it costs more. I'm sure the Tessco catalog has something of comparable performance that comes with test data (heck, you could have the mfr test the very serial number unit they're shipping to you, for a price<grin>)

>
> Pardon my ignorance, but what's that?

More common in power electronics, but basically you put the UUT in series with a known reactance and known resistance, and measure the voltages across all three. Then you can solve for the resistance and reactance of the unknown. Back in the day, this was solved graphically, but these days, you can do with a spreadsheet or calculator. The trick is that there are often 2 possible solutions, but usually, only one is "reasonable".

Yeah, but I'll bet the transmitter in a WiFi node doesn't have a
particularly good match either.. so you could come out better or worse.
3dB loss on top of 15dBi gain is still a net of 12dB over whatever
little antenna there was before (if it was even 0dBi)

well.. good match at 200 ohms... I was thinking 50 ohms, so it's equally
sucky over the entire band.

80 MHz out of 2400 is, what, about 3% BW? that's like 5MHz on a 2m antenna.

these sort of yagis actually are fairly broadband. Note that all the
directors are the same length, too. What they don't typically get is a
lot of gain for the length.

yeah, but using LMR-400 with that $20 antenna wouldn't necessarily be
the expected application. It's sold as a "laptop range enhancer" for
the most part, and I'd expect 3-6 ft of some small (lossy) flexible
stuff. I'd worry about the LMR-400 bending the antenna.

Oh.. I didn't see that.. so the beamwidth and directivity are
consistent. Nice that back of the envelope estimation theory works.

The elements are lossy, aren't they? That will improve the match (and
reduce the gain). Sort of the same idea as the Terminated folded
dipole.. add loss, improve match. And just like for that kind of
application, I think what they're selling here is "some gain, and some
directivity, at very low price"

> be 50 ohms.

I wouldn't.. For that matter, the source impedance probably isn't 50
ohms in the box its connected to. Just looking over some MMIC data
sheets I have here, it looks like they have 2:1 as a worst case and
1.5:1 typical..

This kind of stuff isn't designed like high performance RF systems. They
pick the cheapest amplifier, often don't care much about DC power
efficiency, and cobble up some sort of output filter that keeps the
spurious down low enough to meet Part 15. It's not like specsheets for
consumer WiFi gear actually give you power "at the connector" or
radiated power. All they care is that they don't bust the FCC limits,
and not be "too low" that they'll get consumer complaints.

> on what I can see, feel, touch, understand, and test.

No.. I think its not that they think they have a good match, I think
they just don't care, because in the application, it's "good enough".
They're not designing a deep space communication link where they have to
eke out every last hundredth of a dB to get that 10bps through.

Don't forget that in Region 1, the 2M band is only 2 MHz wide, the
bottom 500 kHz is dedicated to SSB and the top 200 kHz is for satellite.

Sure, that does make it harder. The OP is in region 2, though, where
there's 4 MHz theoretically available)

<flame protective suit on> And of course, a lot of the band plans are
basically gentlemen's agreements and have no force of law. As long as
you don't interfere with someone (challenging in some geographical
locations), you can pretty much do what you want.<flame suit off>

I wouldn't want to put input or output on 144.2, for instance.

But looking at the ARRL band plan, you could put your input up at
147.6-147.99 and put your output at 145.5-145.8 (Misc and experimental,
per ARRL).. not quite 3 MHz, but close, and a whole lot better than 600kHz.

Here in the Los Angeles area, either TASMA or the anti-TASMA folks would
probably round up people to have you tarred, feathered and run out of
town on a rail, no matter what you do. In any case, things move so
slowly that unless you were hideously inconsiderate and egregiously
interfering, you could probably run for a year or more before it would
get too nasty.

There is a 147.585/144.930 pair labeled for "portable repeater" in the
TASMA plan (max 72 hrs/month).. that's 2.5 MHz apart (to make filtering
easier). They also say 144.310-144.375 is for simplex unchannelized,
but I've not heard much on the air there..for an experiment, it would
probably work.

If your intent is to experiment with the cheap duplexer, what I have to offer is irrelevant. However, if you aim to build a repeater, consider getting your isolation over distance (much greater than 10m). Put the transmitter and receiver a few km apart and link them using another band authorized in your area (440?).

I encountered this in Key West Florida some years ago. Worked fine there.

I think he is in Region 1. He posts with 2 callsigns, one is a 4X1
(Israel) and mentions:

but my 2m band is only 144-146
mHz, and the repeater portion is really just 145-146.

> <flame protective suit on> And of course, a lot of the band plans are
> basically gentlemen's agreements and have no force of law. As long as
> you don't interfere with someone (challenging in some geographical
> locations), you can pretty much do what you want.<flame suit off>

Sure, but to get a permit for unattended operation, at least over here,
you'll need to abide to the band plans.

(in fact in my country, Netherlands, it is even worse: the repeater
frequencies are not coordinated by the ham community itself, but by
the equivalent of the FCC. they work strictly by a set of rules
originally drafted by the amateur societies, in the days the bands
were still overcrowded. arbitrary figures were put in those rules
regarding things like minimal desirable distance between repeaters,
maximum height of antennas, maximum EIRP power, that were originally
just there to regulate the inflow of new repeater projects a bit, so
everyone would have a fair chance of running a repeater. if you were
a few km too close, had an antenna a bit high, or similar, it usually
wasn't a problem. but one day an amateur who got refused a license
went to court claiming that others had gotten a license while not being
within the rules, and as a reaction the authority now strictly follows
the rules and refuses every application that does not fully conform to
all the rules. of course, operating on one of the reserved repeater
channels is one of the rules.)

It is done here on 10m, where the duplex offset is only 100 kHz and
a duplexer is physically very large.

However, what I hear from the repeater team is that one is in fact
building and maintaining 2 repeaters, doubling the chance of any faults
and problems. Setting up the 10m repeater was much more work than
everyone envisioned, and many had experience on 70cm etc.

What about VoIP using 802.11 as the link. These days, that might be
easier than trying to cobble up a 440 remote link.

Yup. Two repeaters. But avoiding "cans" just might be a blessing.

My local club has a repeater using new electronics but an old duplexer.
I hate periodically re-tweaking the duplexer but
I'm the only one with the spec-an/tracking generator, so I'm it.

The repeater maintenance budget will handle a new duplexer soon.
Hallelujah!

How fine is fine?

That last time I did that (about 30 years ago), on a commercial system, there was a huge difference in transmit and receive footprint. Some locations could hear but not talk. Others were the other way around. Either way, the customers were not thrilled. We went back to one antenna per radio.

We then repeated the same mistake with a common receive antenna at the very top of the tower, followed by an RF amp, and then an 8 way splitter. Attach 8 receivers and you only need one RX antenna. Unfortunately, the amplifier was too easily overloaded, and the splitter did not provide sufficient isolation to prevent the local oscillator leakage from creating new receiver spurs. I later added cavities and isolators to solve that problem, which increased the cost sufficiently that 8 TX/RX antennas would have been cheaper. (Except for the tower space rental, but we owned the building and towers). Also, with a single RX antenna on 8 radios, it makes a great single point of failure for lightning hits. It was easy to tell if the RF Amp had taken a hit. The office would simultaneously get dozens of irate service outage calls (These were community repeaters with up to 15 customers per repeater). I would never want to be the top antenna on a tower, no matter what the range benefits.

9 repeater in one rack. Notice the lack of duplexers.
<http://802.11junk.com/jeffl/pics/Old%20Repeaters/slides/Santiago-01.html>

Here's the corresponding transmit antenna intermod generator:
<http://802.11junk.com/jeffl/pics/Old%20Repeaters/slides/LoopMtn02.html>
The receive antenna is behind me, on top of another telephone pole.

Yet another great idea was to physically separate the transmitter and receiver buildings on a mountain top. That was Verdugo Pk in the San Fernando Valley. Sorry, no photos handy. This had some real advantages, especially at low band (30-50Mhz). The problem was that with all the transmitters jammed into one building, with little

physical isolation among the antennas, there's was considerable intermod caused by the various TX mixes. Since the original justification for this great idea was to solve the intermod problem, this was also loser.

Much as I don't like duplexers, isolators, cavities, lightning arrestors, fat coax, and omni antennas, the combination is the solution that seems to work the best. All the other great ideas are far worse, more expensive, or deficient in some manner.

<http://802.11junk.com/jeffl/pics/Old%20Repeaters/>

Guess what's happening with this antenna problem?
<http://802.11junk.com/jeffl/pics/Old%20Repeaters/slides/LoopMtn03.html>
Incidentally, that's where I was cleaning up the mess and almost picked up what I thought was a piece of black coax. It was a snake.

Good question. Coverage was entirely satisfactory over the entire island
and several miles up the Overseas Highway. I never used anything more
exotic than a rubber duck. However, Key West is small and all the keys are
very flat.

Thanks for the advice and information.

I'm not in the US. 3Mhz split is more than my entire 2m band. :-(

Acutally that's the real purpose of the whole experiement. We are looking
at setting up a system of internet linked remote inputs (and possibly
low power local outputs) using Linux and SVXLINK.

Right now the final destination is an Echolink type node (SVXLINK also
acts as an Echolink server), but one of the things we wanted to experiment
with is an actual repeater.

Thanks,

Geoff.

That's basically our problem. The repeater we want to use was developed with the criterea that if you parked your car, turned on your 25 watt or higher radio with a 5/8 wave whip and was able to "kerchunk" the repeater, the area was "covered". This coverage was mapped out around 1990.

Since then population has expanded, new housing has been built and new hams have become licensed. 2011 critera is in order to be covered, a ham with a watt HT has to be able to be understood.

The main repeater in question is able to reach the sea twoard the north west to the southwest (about 35 miles), but can't even be heard 2-3 KM to the north in spots, and has almost no reception to the southeast.

Our proposed solution is not radio links as they are a expensive, need to be mainainted on site, etc. Internet remote receivers are very cheap, for example, an HT an interface to the computer and an old P4 (needs built in ethernet) makes a useable one and costs a couple of dollars a month in electrcity. Obvously the location has to have decent internet bandwidth with 64k bits per second spare.

Performance can be improved with a better radio and antenna, but in some places, there is only one ham that needs to be "covered".

There may even be real money for real equipment later, but not now.

Geoff.

That's our problem. Jerusalem is high (3,000 feet ASL) and loaded with hills. There are spots in the city where there is no cell phone coverage. The cell phone companies go nuts trying to fill the holes, but there is a lot of NIMBY here.

At first they used (or planned using) an FM link on 23cm, then they
switched to digital voice over 802.11a (6cm), then to 802.11g on 13cm,
and I think they now use a wired internet connection.

If you have two antennas you don't need a duplexer. Just notch the
transmit from the receive antenna.

I think that is what he is asking. Can he takes his duplexer and use
it as an extra sharp notch filter for his receiver. One "side" is
already set up for that purpose. He is asking if the "side"
originally intended for the transmitter can be used to further filter
the receiver.

2161. duplexers, antennas, repeaters

One wonders why someone isn't pushing for a digital TDMA scheme for amateurs. You could build a very nice full duplex repeater on a single frequency that way. Sure it's totally incompatible with current FM repeaters, but then, D-star isn't totally compatible either. D-star and it's ilk are sort of half measures in that sense.

No filtering, much less intermod issues in multi station at onee site systems... all kinds of good comes of it.

Digital schemes on HF to replace SSB I can see having real trouble (the biggest is the lack of a "party line" capability, the other is the long propagation delay on HF paths), but on VHF and up FM, you already have a "one person talks at a time" by virtue of the standard FM demodulator.

Oh, they have their problems!

I picked up an MFJ-949E manual HF tuner at a local swap meet . At home, I opened it to give it the once-over. Good on me. Most of the nuts and bolts in the RF path were quite loose and none of them were completely tight -- and we're talking about my using a nut driver with three fingertips, not a lug wrench with two hands.

And I assume you bought it used. I don't remember seeing
MFJ vendors at the swap meet. So.... The hardware was loose.
You don't know for a fact that it came from MFJ that way.

Or, the original purchaser had no idea why it didn't work
when he bought it new and sold it without any comment other
than "New in the box".

I had that happen with an SO-239 connector on the back of an MFJ tuner.
One of the pop rivets was loose, possibly from the factory, more likely
from being banged around my home.

I drilled out the pop rivets on that connector (the others were all fine)
and replaced them with bolts, nuts and lockwashers. It's fine now.

While we are talking about MFJ products, I had a 20 meter CW rig from them
that I bought in 1995 stop receiving properly in 2010. I filled out a
"support request" on their website and the guy who designed it sent me an
email.

A drop of anaerobic threadlocker would be a better solution. Most
commercially manufactured equipment these days doesn't use lockwashers
for good reason, unless it's a "heritage design" where they're counting
on the thickness of the washer or something like that.

Picking the right chemical is important (wicking vs non-wicking, various
break strengths, various cure times, etc.). Don't use Loctite 241 red on
4-40 hardware you ever want to remove.. it's stronger than the metal..
the green 290 is great stuff for "post assembly" use.

A good number of years ago I bought the MFJ-948 tuner. It was bought new from a large dealer at a hamfest. Same thing. It raddled when I got it home. Atleast one nut if not more was loose in the box. I had to tighten many of the screws/nuts in it before I put it on the air.
I compaired the wattmeter to a Bird and a good dummy load. It was way off. When calibrated on one band, it would be way off on another. Finally calibrated for 20 meters and let it go at whatever on the other bands. All I ineeded for is to watch the reflected power and tune for minimum. I have several other meters to actually check the power if I need to.

The only other MFJ item I have owned was a 1270 Packet unit. First one was bad out of the box, but to their credit, when I called, they shipped me a new one and I got it in about two days. I sent the other one back. The new one worked as I expected it to as long as I had the packet station going.

I agree with you, Tom, mostly. However, about 10 years ago I bought an MFJ 259B. I thought when it said it measured impedance, it meant magnitude and angle. When I called them, they said NO. They thought impedance meant absolute magnitude. It was a great disappointment.

Within a few weeks, it became erratic at some frequencies. I bought other equipment to check it out and found that the 259B was pretty much lying to me.

It is now in my junk bin.

Don't ask me about the headphones I got from them.

Always a risk buying used ATUs. As noted earlier, it is easy enough to do permanent damage to a '949E with a 100W transmitter.

Re the loose nuts... so you got one that look like it is factory fresh. Loose nuts, nuts floating around loose in the case and loose lumps of solder are commonly reported in new product, mine was that way (a few blobs of solder and a spare nut).

Is it unfair to say that buying some MFJ products is a bit like buying an unfinished kit?

Now for something constructive, now that you have put the case back together.

Would you like the PEP meter function to work properly (instead of 'truly'). There is provision for a transistor and couple of related parts, <50c worth in all, that are not fitted to the board, presumably as a cost saving measure. If you populate those parts, the think WILL require 12V for the PEP function, but it will work properly, well pretty well.

Unfortunately, it is a half hour job to fit the parts post production.

Not new, no box and the unknowns dominate. I got no information from the prior owner (SK). I also don't know for sure that it left MFJ without lock washers. I don't know if it spent any time bouncing around in a car or truck.

My remarks were not intended as an overarching expos&#65533; of MFJ gear.

>If I send the the dimensions....

Ummm.... please don't do that.

> Just kidding!

Whew!

Interesting MFJ-1804 biquad antenna. In order to get 12dBi gain out
of something like that, it would either need to be 2 biquads and some
kind of power splitter, or one of those extended biquads as in:
<http://www.larsen-b.com/Article/201.html>
or the overkill version at:
<http://www.digdice.com/diy-wifi-antenna-double-dual-biquad-16-17-dbi/>
or maybe a biquad-yagi conglomeration:
<http://www.digdice.com/biquad-yagi-24ghz-antenna/>
Of course, MFJ supplies no specs, no manual, no dimensions, no test
results, no test procedures, no graphs, and no clue what's inside. For
$60, I would expect better, especially since I can buy something as
good or better for much less:
<http://www.l-com.com/item.aspx?id=21808> (3 element loop yagi)
<http://www.ebay.com/itm/170628411340> (4 element patch ant)

Looks like MFJ has a line of 2.4Ghz products, that don't seem to be
easily found on the product listing pull-down.

I had a similar experience. I friend loaned me some monstrous MFJ
antenna tuner, probably just to get it out of his crowded shack. I
tried to characterize the tuner to see what it would do, and
immediately ran into stability issues. I couldn't get consistent
sweeps and measurements. I eventually beat on the case and noticed
that the scope traces were moving. That was traced to numerous loose
screws and to marginal solder connections. It took a while to get
everything tightened down properly. That fixed the stability problem.
Even fixed, it took me another month or so get convince my friend to
take it back. I don't really need a kilowatt tuner for my 100w
radio(s).

Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.

Look at SVXLINK. It's an open source package that runs on Linux (and possibly BSD) that does exactly that.

It includes support for remote receivers (with a voting option), remote transmitters, and an echolink server.

We plan to use it with hard wired internet links, but who knows, an 802.11 link could work. Unlike the US we are restricted to 100mW EIRP, so no gain antennas, etc, to make things work better.

This is the grounding of an antenna coax to the chassis of a tuner. The wrong stuff in the wrong place would be a disaster. At least with lockwashers, I know there will be a good contact.

Do you have a transmit ban on 802.11 channels in 4X too?

We as hams in the Netherlands are no longer allowed to transmit above
2400 MHz except to an amateur satellite.

There is a limit of 100mW EIRP for 2400-2450 mHz for terrestrial use,
with a limit of 100W EIRP to satellites in the 2400-2402 mHz part of the
band. This is from a document on the Ministry of Communicatons website,
dated 1999. It has been unchanged except for the addition of 7.100-7.200 mHz
so they never bothered to update it.

The difference between a 100mW limit and an outright ban in practice is
very little IMHO.

For example, you can turn off encryption and use a WiFi device as a packet
radio, or you can call CQ on your cordless phone. :-(

> I wonder how important matching is for a pure direction finding antenna,

I don't think it affects sensitivity, which is not really at a premium anyhow.

A gamma match seems to skew forward-max location a bit to one side, which matters if you're relying on accurate bearings from a distance, but overall it doesn't matter much - in some ways it's better to expect to spiral in on the fox a little anyhow, I reckon.

The gamma match also goes wonky if you put your hand on it, but I guess that's not surprising. many of the top competitors use them anyhow - we have a design that's easy to disassemble to put into a suitcase for air travel.

One of the guys built a much-enhanced version of the NEC software for the Mac, and he's automated it to automatically optimise (millions of individual runs with different combinations) a 7-element boom for 70cm, which is yielding very impressive DF results right across the band.

Clifford Heath.

Ya, I have my doubts about the 12 dbi gain figure. I have built a few
biquads, (with your feed point correction), it has amazed me how easy
it is to make them work (at 2.4 Ghz), I always thought the short
wavelength would cause many dimensional errors. Yes, they work, what
does "work" mean :-)
I've settled on a flat panel antenna for my boat antenna
(15dbi manu. spec.) At one time I had a dish with biquad feed, but it
was to tight, when the wind blew or tide changed it would miss the target.
Do you believe the 20 dbi figure?

2189. Round & round the rugged rock

Newsgroup: rec.radio.amateur.antenna
Date: 2011-09-01 17:01:54 UTC
From: Sniff ma Diff! <banjobusters@grand.old.opry.com>
Message-ID: <ipdv575oft70bb4lfh66i9hbemnfhdg10n@4ax.com>
Source record: 3890

Just discovered a dinky 20m yagi. made from wooden dowel with an 8ft square section to connect the two ends, the electrical parts are simply wire where required.

Being 8ft across the ends and slightly more lengthwise to allow for a turning radius, it looks like it could fit in my loft. I already have a lightweight rotator that could handle that. I think it was supposed to be a caravan tv aerial originally.

To make things even lighter I wondered if I could use pvc conduit with alloy tape as the elements? Either way I think ist worth a go.

My problem is my rotator, it has twin core cable from its little remote, so theres no way to determine where Im pointing.
So thats my query, anyone any ideas how I can show something downstairs, while this is turning in the loft?

Best I could come up with is to use some sort of lighweight motor/gears arrangement to work a pointer, by splitting the feed cable in two and using one as a feed for that,perhaps that would work?

1) It stops at one point and must be reversed.
2) It cant turn continuously.
3 Dont know how real ones work at all.
4) No idea if a proper one can be jury rigged ro work here.

Everyone lies about gain, but that's ok because few people can measure
the gain (and get reproducible results).

For a given physical size antenna, high gain antennas imply narrow
bandwidth and critical construction. On the other foot, low gain
antennas, such as the biquad, is fairly broadband, and therefore not
particularly critical to construct. What's fun is to attach the
antenna to a reflection coefficient bridge or directional coupler,
<http://pe2er.nl/wifiswr/>
<http://www.qsl.net/n9zia/rlb/texscan.png>
<http://www.qsl.net/n9zia/rlb/>
sweep generator, and oscilloscope to look at the VSWR curve. Then try
moving things around. On my crowded workbench, location of the
antenna relative to the highly reflective test equipment make a huge
difference. The changes do not really have a big effect on antenna
operation, but they certainly present a different picture as compared
to the nice clean curves on the data sheets.

> Do you believe the 20 dbi figure?

I guess you missed my previous rant on the subject. I bought two of
those yagi antennas (for $6/ea incidentally) just to see what was
wrong with them.
<http://802.11junk.com/jeffl/crud/wi-fi-yagi-that-sucks.jpg>
Notice the really crude dipole driven element hiding under the
plastic. That isn't going to work. No balun, no matching, exposed
coax wires, and offset from the center line too much. Some tests
showed that it has more gain to the side than towards the front. I
also suspect that the rather large size boom diameter was not
considered in calculating the element lengths. A piece of total junk,
but at the price, probably sells well (which is why I like the antenna
biz).

The above yagi is apparently a cost reduced clone of a similar yagi
that does have a proper feed and a more realistic gain claim. I think
(not sure) that this is the one:
<http://www.ebay.com/itm/250847584296>
I have no idea if this one works any better.

This is a more reputable source:
<http://www.comtelcoantennas.com/yagi_1_8_2_4_ghz.htm>
Note the radically higher prices and the 14dBi gain for a 16 element
yagi:

In my experience, PVC conduit tends to sag if used for horizontal
elements... it needs to be supported every few feet or it will
"droop".

>My problem is my rotator, it has twin core cable from its little
>remote, so theres no way to determine where Im pointing.
>So thats my query, anyone any ideas how I can show something
>downstairs, while this is turning in the loft?

That depends a lot on just what sort of rotator it is, whether the
remote is intended to have any sort of display, etc.

Some old-style TV rotators were intended to be "self-aligning" by
means of a clutch... turn the knob all the way clockwise, wait until
the antenna stops rotating, turn the knob all the way
counter-clockwise, wait until it stops, and you now know that the
antenna is certain to be all the way at one end of its travel (e.g.
due northwards, if that's the way you originally mounted it) and you
can rotate it back to any desired direction.

If worse comes to worst you may need to add some sort of extra readout
sensors - e.g. a multi-turn potentiometer, linked to the rotating part
of the mast through a belt or idler-pulley arrangement - and run an
extra set of sensing wires down to your shack.

>Best I could come up with is to use some sort of lighweight
>motor/gears arrangement to work a pointer, by splitting the feed cable

Depends if the feed cable has a separate ground (braid) or is just the
two leads.

I think we need more details on just how your rotator works (and is
wired) and how the antenna is wired up, to offer good advice.

The rotator is a pretty simple affair, the lead is bellwire, straight two two core bellwire. It stops same place every time either way so the internal gears ,must be doing something right.

My apologies though....I think Im in the wrong NG? I reinstalled my reader and may have screwed that up a little, I noticed I could upload pics so I tried that with a simple osc diagram, which refused to go. I dont want the Mod thinking he had some incoming pornfest on the way, my call is indeed my own verifiable callsign here in Scotland if you need to verify.

Thanks

There isn't a USENET moderator, per se, in this newsgroup.

However, many USENET providers do honor the "No binaries here!"
charter for this group, and won't pass along articles that contain them.

Now... as to a solution to your problem. One might be the approach I
think you were thinking of - use one lead in the bellwire for power,
the other for a readout signal, and use your building's grounding
system as the return for both. This would probably work, but I don't
recommend it... mains-wiring earthing should really be used only for
safety purposes and should never carry currents. In the event of a
wiring fault, you might find your antenna-rotor system carrying some
very high fault currents (many amperes) and could expose yourself to
shock and equipment damage.

One simple approach would require no new equipment or wiring at all,
except a wristwatch. Simply figure out how long it takes your rotator
to go all the way from one end of its travel to the other. In order
to aim the antenna to a specific direction, rotate it all the way one
way (maximum turn time) and then rotate it back for a variable amount
of time based on the direction you want it to point. As long as the
rotator "clutch" can stand to spin against the stop for a full
rotation-time, this should be safe enough. If the rotator doesn't
have a clutch - if you're actually "stalling" the motor when it hits
the end-stop - then you shouldn't keep running it past this point
(might overheat the motor) and should stop rotating when the motor
stalls and the current jumps upwards.

There are plenty of fancier approach which could be tried, which would
carry both DC power to the rotator, and some sort of measurement
and/or control signal, over the same cable. The latter might be
carried as an audio tone, for instance.

For pics, put them on a website and post the link here. Many do that. Easy to use is Picasa; others may be easier.

Powering the rotator usually involves applying 28 - 36 VAC. One side of the AC is tied directly to two coils in the motor; the other end of those coils is tied to the other side of the AC, one directly and the other through a capacitor. Direction of rotation is established by which coil is fed directly.

I know of three ways to indicate the rotator's position. One uses a tapped resistor to send a portion of the applied voltage to the controller, which has a meter in it. It only indicates when power is applied (during actual rotation).

The second uses a make-break contact in the rotator to send a sequence of pulses to a spring-loaded stepper during rotation. It indicates the position with a mechnical pointer on the controller. Indicates always.

The third has a small motor in the controller, turning an indicator at (we hope) the same speed as the rotator. Indicates always.

If you can determine that your rotator uses one of these, maybe we can take you and your rotor to the next level.

The beauty of usenet is it allows all sorts of characters to post. Typically, in response a simple question it turns into some insane "How esoteric and complicated can I make this?" contest.

So, with that thought in mind....

You have a rotor, you have two wires between your radio shack and the rotor.

Since everyone seems to think that broadband over power lines is such a "Good thing(tm)" here's a solution to your problem.

Use your two wire feeder to supply a fixed AC voltage to run the controllers and the rotator.

Feed a digital control signal up the power line to tell the rotor which way to turn.

Feed a digital signal back down the power line with the telemetry to feed a display of which way the rotor is pointing.

Obviously since you have a bi-direction data stream on the power line to the rotor, you can get as complicated as you want with the amount of extraneous details. Such as slow start, brake clutch on and off.

In fact, since you're already in the roof, add a weather station outside and feed that data back down too. ;-)

I like that wristwatch concept. But the quoted passage gave me another idea. If the stalled rotor current is appreciably higher than the operating current, then that's his end-of-travel indicator, right there. I can check it myself and the OP will also need to.

That's a pretty good assessment. I'm even willing to put up with it for the price.

The way I figure, if I have a professional business that I need to buy equipment, I'm going to buy top notch equipment that I can depreciate as part of the business.

In my personal life, I have a bit tighter of a budget. So I'm willing to tighten screws and do the final QC on the stuff. I'm going to open the case and have a look around anyhow.

>You're building a CW radar, basically.
>That's how near field ranges work, too.

Yep. Also known as a proximity detector and possibly a really bad
interferometer. I can see cars driving by, people moving around in
the house, trees swaying in the wind, and the opening and closing of
doors and windows. These are all easy to identify on the sweep
because they all move around. Only the major dip in the VSWR curve,
near resonance, remains fairly stable.

Back to MFJ bashing... On my desk is yet another MFJ-259B for
repair, probably with the two blown shottky diodes that I previously
mentioned. One of the local hams heard me talking about the problem
over the local repeater, and decided that maybe I could fix it for
him. Usually, they wait until the week before Field Day for such
repairs but he's installing a tower next week and wants it fixed
yesterday. Sigh.

Have you discussed this with Martin Jue? I think it's rude to bad-mouth a fellow ham behind his back. I don't see how the diodes are a problem, if you follow directions. If you live somewhere dusty or snowy and dry enough to make static, use a gamma match or an UnUn or some other means to keep your antenna at DC ground. I have been using germanium diodes for 50 years and can't remember frying one in a small signal RF application. What does Martin say about bleeder resistors?

I have a 4" pigtail around the ground lug and a male banana plug on the end that lives in the middle of the SO-239, unless I am making measurements. I use the banana plug as a shorting stick to neutralize any residual capacitive charge in the device/coaxial cable under test. Center conductor to cable ground. If I am especially concerned I'll groung the 259B to my extensive safety ground system. When dealing with little diodes you always want to make sure none of the sparks go through them. Ground, ground and ground.

>Have you discussed this with Martin Jue?

No. I don't own an MFJ-259B. This is my 3rd(?) repair for what
appears to be exactly the same problem. I don't see how calling MFJ
will prove anything as they are apparently aware of the ESD problem.
See quotes from manual below.

I also reverse engineered the MFJ-1800 antenna, and also decided that
it has a problem. I have not called MFJ on these issues. Too busy
and too lazy.

>I think it's rude to bad-mouth
>a fellow ham behind his back.

Would you prefer I keep it secret and not tell fellow hams how to fix
it and why I think they blow up? I believe that I clearly labelled my
guesswork as conjecture and not fact. If hams were only allowed to
discuss things that are absolutely certain, the airwaves would be
silent.

>I don't see how the diodes are a problem,
>if you follow directions.

The units that are failing are not mine. I have no control over how
they are used.

As I vaguely recall, one failed while connected to some HF wire
antenna, the 2nd failed while plugging in a variety of calibrated
loads on the bench, and the most recent failed while attached to a
mobile HF antenna. It was difficult to determine the exact cause of
each failure because the unit did not just die, but instead started
producing insane readings. In all cases, the user thought something
was wrong with the antenna or loads, not the MJF-259B.

>If you live somewhere dusty or snowy and dry
>enough to make static, use a gamma match or an UnUn or some other means
>to keep your antenna at DC ground.

Attach a high impedance voltmeter to a wire antenna blowing in the
wind and note the DC voltage produced. In my area, the humidity
rarely goes below about 30%, so static build up should not be a
problem when attached to an antenna. Currently, the humidity is
80-90% (morning fog), but when we get the hot dry winds from the
desert, the humidity will drop sufficiently low to cause problems for
a few daze.

What I believe is killing the diodes is not RF. It's the user
building up a static charge on plastic seat covers, synthetic clothes,
plastic carpet, etc, and discharging it into the antenna connector
when plugging in the antenna connector. Incidentally, one of my
customers with chronic equipment failures was traced to a negative ion
generator, which produced impressive high voltages on nearby object.

>I have been using germanium diodes
>for 50 years and can't remember frying one in a small signal RF
>application.

How many of these germanium diodes were directly connected to the
antenna connector?

Apparently you missed my previous rant on the topic. See the
schematic extract of the RF section at:
<http://802.11junk.com/jeffl/crud/MFJ-259B-RF-section.jpg>
Notice the directly connected diodes. The diodes in question are
Avago HSMS-2820 zero bias shottky diodes.
<http://www.avagotech.com/docs/AV02-1320EN>
15V Max PIV is rather low. It won't take much voltage at the antenna
go exceed 15V. The two 47K resitors going to 0.01uf bypass caps make
an effective ground to any fast risetime voltage spike at the antenna.
An important clue is that BOTH D3 and D4 appear to be blown each time,
which implies an external failure, not a component failure.

>What does Martin say about bleeder resistors?

I don't know. I haven't discussed this or any of my allegations with
him or MFJ support.

>I have a 4" pigtail around the ground lug and a male banana plug on the
>end that lives in the middle of the SO-239, unless I am making

>groung the 259B to my extensive safety ground system. When dealing with
>little diodes you always want to make sure none of the sparks go through
>them. Ground, ground and ground.

Yep. That's a good way to provide some protection. However, there's
no protection while you're juggling connectors when you run the risk

of a static discharge to the center of the coax connector.

I don't recall reading such a procedure in the user manual. However,
there are plenty of warning:
<http://www.mfjenterprises.com/pdffiles/MFJ-259B.pdf>
In section 4.1:
WARNING: NEVER APPLY EXTERNAL VOLTAGES OR RF SIGNALS TO THE
ANTENNA CONNECTOR.
and in 5.1:
WARNING: NEVER APPLY RF OR ANY OTHER EXTERNAL VOLTAGES TO THE
ANTENNA PORT OF THIS UNIT. THIS UNIT USES ZERO BIAS DETECTOR
DIODES THAT ARE EASILY DAMAGED BY EXTERNAL VOLTAGES OVER A
FEW VOLTS.
and in 5.2:
WARNING: NEVER APPLY EXTERNAL VOLTAGES OR RF SIGNALS TO THE
ANTENNA CONNECTOR. PROTECT THIS PORT FROM ESD.

Clear enough. It would appear that MFJ is fully away of the fragile
nature of the input circuitry.

Hmmm.... The problem might be the SO-239 connector. When you plug
something into that connector, it connects the center pin first, and
then the ground. If it were replaced by an N connector, the ground
would make contact before the center pink, thus offering some added
protection. I'll see if the connector can be replaced.

<http://www.w8ji.com/mfj-259b_calibration.htm>
Most Likely Failures

Other than manufacturing errors, the detector diodes clearly
stand out as the most common problem. They are the most easily
damaged devices in the analyzer. If you have a sudden problem,
it is most likely a defective detector diode. Diode damage almost
always comes from accidentally applying voltage on the antenna
port.

Why are the diodes so sensitive? In order for the detectors to be
accurate within a fraction of a percent (one bit), detector diodes
must have very low capacitance and a very low threshold voltage.
This means the diodes, through necessity, must be low-power
zero-bias Schottky microwave detector diodes. The same
characteristics that make them accurate and linear cause the diodes
to be especially sensitive to damage from small voltage spikes.
ALWAYS discharge large antennas before connecting them to the
analyzer! Never apply external voltages greater than 3 volts to the
antenna port!

and

Because the detector is broadband and because it is dc coupled
to the antenna, any external voltage across the input port
causes measurement errors. It is the accumulated voltage of
multiple sources that is most important, not the strength of
any individual signal. Because of that, large antennas should

be tested at times when propagated signals in the range of the
antenna's response are at minimum strength.

W8JI designed the MFJ-259b.

Hi Jeff,

I'm sure you are perfectly aware of the single point of failure in
that generality.

Few Caps exhibit 0.01uF (when so marked) to transients (where it is
presumed they will exhibit 1/2*pi*f*c reactance to the risetime).

When we (silverbacks) got into this game, (the preferable) mica caps
were available, snipped out of the nearest sacrificial TV or radio.
Trying to read those several styles of color coding was the biggest
hurdle, but I had plenty in my junk-box.

Ceramic is ubiquitous, now, and far from choice in these matters,
unless you do deep research (maybe).

You got any favorites that respond to this?

I am? Ummm... well, I guess so.

>Few Caps exhibit 0.01uF (when so marked) to transients (where it is
>presumed they will exhibit 1/2*pi*f*c reactance to the risetime).

True. They all have some internal resistance to overcome. However,
that's negligible resistance when compared to that of a static blast.
Static electricity has lots of potential (volts), but is only able to
deliver small amounts of current. That's why we don't get
electrocutes by the potential (voltage) difference between our head
and our feet. Dividing the large voltage, by the tiny current,
results in a fairly substantial source resistance. I'm too lazy to
look it some real numbers, but I'm sure it's in mega ohms. The 47K
resistance, and whatever ESR the 0.01uF contributes, has little effect
on the energy delivered to the shottky diode.

Incidentally, if the source resistance of the static blast was much
less, then the diode would not simply be fried. It would probably
explode.

>When we (silverbacks) got into this game, (the preferable) mica caps
>were available, snipped out of the nearest sacrificial TV or radio.

Dumpster diving in Henry Radio's trash can in West Smog Angeles was
one of my favorite after skool exercises. Salvaging old TV chassis
and dead tubes were the grand prizes. Silver mica caps came a close
second.

>Ceramic is ubiquitous, now, and far from choice in these matters,
>unless you do deep research (maybe).

Ceramic is cheap. I was a big fan of porcelain caps from AVX in big
power amps. If you wanna handle current, there's nothing better.

Silver mica would get hot, ceramic would explode, and everything else
was either too big or too expensive.

Incidentally, I don't think they make 0.01uF silver mica caps. The
biggest I played with were in antenna tuners at 4700pF (or should I
say uuF for nostalgia purposes).

>You got any favorites that respond to this?

I don't understand the question. Favorite what?

It goes beyond that. Extrapolating from power applications hides the
defects of ceramic.

At HF/VHF and above, successful applications comes from throwing uF
solutions at pF problems. Ceramic's performance reveals inductive
reactance above 1-10 MHz. ESR also exhibits the same turn-around in
the same frequency range. Ceramic temperature coefficient is (Y5V)
goes into the toilet in weather that most of the south and eastern
seaboard has seen this summer. XR7 voltage coefficient causes
capacity to plummet at the voltages you offer for static. Over time,
ceramics lose capacity for simply having been in service for a while.

Aside from that, they work fine.

> I was a big fan of porcelain caps from AVX in big
>power amps. If you wanna handle current, there's nothing better.

However, those ceramics are 1,000 times (min.) larger than what you
have recommended. They serve an entirely different agenda.

AVX discusses these issues in much the same terms (for those larger
caps too) at:
http://www.avx.com/docs/techinfo/mlc-tant.pdf

>Incidentally, I don't think they make 0.01uF silver mica caps. The
>biggest I played with were in antenna tuners at 4700pF

Where there is every chance that one silver mica head-to-head with the
ceramic actually exhibit better performance (protecting the diodes).
Perhaps with the scarcity of silver mica, however, 10uF ceramics would
make do (it is not like any precision is demanded to force a selection
of 0.01uF which is boilerplate recommendation from the 50s).

I learned to ground everything working on transmitters the size of
houses. The B+ is bled and grounded when you open the door, but you
still ground anything metal before you touch it. It translated nicely to
CMOS procedures on the bench. I am a grounding fool because I know any
conductor can store a charge lethal to solid state and that any friction
produces a charge. (I humidify, too!)

Such an extreme RF environment is not necessary to blow up the diodes.
None of the 3ea MFJ-259B boxes that I replaced required a transmitter
the size of a house to blow up. Much as the protective procedures
that you are recommending are genuinely useful, the instrument first
has to protect itself.

Assuming they were all fried by ESD, I tried to conjur a method that
would protect the existing design. As simple bleeder resistor to
ground will only help under trivial situations. The worst case
senario, of holding the instrument in one hand, and plugging in a
PL259 that is connected to an ungrounded antenna with a large static
charge, is all too common. Changing to an type-N connector will help
because the grounded shield is connected first, instead of the center

conductor, as in the SO-239.

Back to back diodes might work if the RF levels are low enough. The non-linearity of the diodes will cause measurement accuracy problems and rectify any off frequency RF going into antenna connector.

I'm tempted to try 1:1 RF broadband transformers which should work over octave frequency ranges. Better yet, a tuned 1:1 RF xformer, to improve the front end selectivity so that it can be used in an RF polluted environment[1]. That would work, but will also be very clumsy and expensive.

I know of several devices where failure is sufficiently common, that spare parts are included with the instrument, and the components are in easily accessible sockets. While not a great solution, it does make some sense.

Other than attaching a grounded anchor chain to the MFJ-259b, spraying holy water around the area to increase humidity, or carrying various anti-static protection devices, do you have any suggestions as to how the instrument could better protect itself from ESD?

[1] Attaching a wattmeter to the typical VHF antenna on a mountain top that is colocated with FM/TV xmitters will show a watt or three of RF. The front end of the MFJ-259b is not going to like that.

That's not a problem. In order to get obtain decent bypassing across
5 octaves of bandwidth (2-30MHz), one needs to have multiple capacitor
values and types in parallel. The self-resonant characteristics of
the capacitors is the limiting factor. At some frequency, every
capacitor, and its associated lead inductance, will exhibit an
impedance dip commonly known as series resonance. Below this
frequency, the capacitor will look ummm... like a capacitor. Above
this frequency, it will be more like an inductor.
<http://www.ecircuitcenter.com/Circuits/cmodel1/cmodel1.htm>

None this has anything useful to do with the 0.01uf caps in the
instrument. The diodes are in series with 47K resistors, which are
much larger than any inductive reactance that the 0.1uf bypass
capacitor might present. Since the MFJ-259b only works well up to
maybe a 10:1 VSWR or 5Kohms, the 47K is sufficiently larger than
whatever reactance is presented by the 0.01uf to make the capacitor
characteristics to not be an issue.

While component selection and circuit design are interesting topics,
the current problem is MFJ design quality, MFJ-259b, ESD protection,
and chronic detector diode failures.

I just downloaded the free trial zip file and scanned it. It came up clean and had a size about 3 MB. I set up to unzip it and repeat the scan, but the unzipper reported no files to extract. There were no other errors reported, like cannot find file, corrupt file -- simply no files.

Others, please post your results if you try the free trial download-and-unzip process. TKS.

Argh. I just started working on the analyzer, and found a few errors,
all of which are my mistakes.

1. The antenna analyzer that arrived (3 days late) today is not the
expected MFJ-259B but an MFJ-269. The difference is that the MFJ-269
goes up to UHF frequencies. The front end is similar, but not
identical.

2. The MFJ-269 has a type-N connector, while the MFJ-259 has a UHF
SO-239 connector. So much for the idea of substituting a type-N
connector.

3. Despite my idea of installing a bleeder resistor on the antenna
connector to drain off the static charge, the antenna connector
already shows 50 ohms resistance to ground. I missed this path
because of the rather difficult to read schematic of the MFJ-259 RF
section at:
<http://802.11junk.com/jeffl/crud/MFJ-259B-RF-section.jpg>
The path is from the antenna connector, through R24, L11, and then to
ground.

The MFJ-269 schematic is easier to read at:
<http://802.11junk.com/jeffl/crud/MFJ-269-RF-section.jpg>
which goes through R88, L12, and then to ground.

What bugs me is that the diodes are blowing up despite this rather low
resistance to ground. Either hams are finding some rather high power
ESD sources with which to blow up their analyzers, or some other
failure mechanism is involved.

I haven't finished working on the MFJ-269 quite yet. A report and
photos when I'm done.

I've had more than one device damaged while operating around High power equipment, with probable RF in the shack excursions. My MFJ analyzer, an old Sony camera that had it's floppy drive head destroyed, and a couple other things I cannot remember.

I haven't had any problem with the analyzer since installing my dummy load on it.

But that brings up something interesting. You're reading 50 Ohms on the input connector? Isn't that going to make *all* readings somewhere near 1:1?

Simply change the extension to rar instead of zip and it will extract just fine.
This does not instill confidence in this person/company. I only downloaded it to
check for you, and now we have the answer.

Is it possible that 50 Ohms at DC is much higher Z at MF/HF/VHF?

That is an internet radio tuner with fake buttons. $40 is a lot of money to spend on make-believe. You can buy a real radio for $40 (a nice one if you shop around).

Sure, salvage some components out of some dead mice or printers and come up with an optical positioning indicator using the salvaged IR emitters and receivers. A simple cardboard disk with slot(s) that will let you know when it is in certain positions. The more you use, the more accurate the positioning. You could make it simple, or more complicated by encoding the signals. You didn't say you couldn't run new wires, just asking if you could send a control signal down one of the wires already there, so I hope this isn't a complete waste.

Yeah, I get it: knowledge base software (shouldn't it be knowledge
baseD software?).

Does it use fact base(d) data, or is it belief mode compatible with
Rick Perry science? The simple entry of his name guarantees 34
Million hits in search engine traffic. I would suspect all of that is
free user generated content and tea party organized.

Thanks, Bob,

Funny but unrelated to this file, I downloaded a different .rar a few days ago and discovered it needs an extractor I didn't have. Now I really have to get that rar extractor. Who owns the rar code rights and why do they hate zip??? :-(

That changes things for me. Over and above ham gear, I already have a dozen
or so real radios, a standalone Internet radio (Livio) and I have
I-Heart-Radio (free) on several computers.

I was imagining this download was a client front-end for a bank of SDRs
hooked to servers, a la a multi-user remote base. Guess not.

I've used 7-zip for years and haven't needed any other program to
compress / decompress files. It's free and does a damn good job at
compressing files too.

Are you using WinRAR? It's pretty much the de facto standard in the binary groups. As I told the OP, I wouldn't trust any program that archives a file in RAR and labels it as a zip format. I suspect this program does it to avoid having to pay license fees to use a what many feel to be a superior archiving program format. Apparently the archiving program thinks that RAR is better as well otherwise I think he would stick with using the zip archive code.

If you look at the circuit, there is a DC path from the centre pin, via the 50 ohm resistor that forms part of the measurement bridge, and an RFC to ground. That would look like 50 ohms at DC, but it will not prevent the measurement bridge working in the way you suggest.

But the reality is that people do damage these things... and so the method you suggested earlier is not likely to be sufficient to protect them.

I am careful to avoid connecting an instrument of this type to an antenna system unless I have drained any static charge first, and avoid other transmitters on air nearby.

An easy trap is to connect the analyser or the like to an antenna, then start working on the antenna without considerig the risk of introducing a spike during the work.

Painful, but worth disconnecting immediately after each measurement. Not as painful if BNC connectors are used.(Why did they build those things with SO239... don't answer!)

I think you are correct. I do think that more care needs to be taken with these devices than with a lot of other electronic items Hams use. I liken them to RF attenuator blocks. You see a lot of them in company repair shops, because people are often trying to put too much power through them.

After getting the new replacement analyzer, and using the dummy load, and I do the static drain too, plus I keep it away from other people, it's lasted FB.

I used to have a Sony Mavica MVC-FD73 camera. Nice camera for 640x480
closeups. I gave it as a present to a friend, who bashed in the LCD
display. I repaired it, and she bashed it in again. I gave up.

Per one of my previous postings, none of the failures coincided with
any high power RF nearby. One was connected to an antenna when it
probably failed, but there were no transmitters active. I've tried
interrogating the owners and none claim that they did anything
potentially destructive. I've been assuming it was ESD, not RF that
is killing the diodes, but I'm not sure.

I just tested the diodes. 3 diodes were open, one was ok.

>I haven't had any problem with the analyzer since installing my dummy
>load on it.

Probably a good idea.

>But that brings up something interesting. You're reading 50 Ohms on the
>input connector? Isn't that going to make *all* readings somewhere near 1:1?

Owen answered that question. L12 (100 uH) is in series with the 50
bridge "load" and therefore allows measurements to be made without
padding the antenna with an additional 50 ohms.

I threw together a web page on the MFJ-269 repair:
<http://802.11junk.com/jeffl/MFJ-269-repair/>
Hopefully, this will help anyone following my succession of mistakes
and screwups. I'm not really done as I want to verify that it's
working correctly and hopefully not require recalibration.

Incidentally, no lock washers on any of the screws inside.

That is probably key, don't trust other people... and be pretty wary of one's self!

It is interesting you mention the Other Persons thing... I am in the process of drafting a web article commenting on the advice that is so common these days on online fora, "can you borrow an analyser?..."

This is almost always offered to some newbie who is having trouble "tuning up his antenna".

Most don't understand complex numbers, impedance, transmission lines, etc etc and someone tells them get an analyser and tune for resonance. I can only guess that the advisers are equally lacking in knowledge and experience, but I will concede that the analyser dumbed down to a VSWR meter with self contained RF source than can be tuned outside band limits, can be a pretty handy thing.

But despite the fact that adjusting many, if not most antennas for minimum VSWR is the sensible objective, the resonance brigade chimes in with make X zero looking into some arbitrary length of feed line, a condition which isn't always associated with minimum VSWR and may actually not be achievable. Some newbies have clipped their mobile whip away to make that discovery, but perhaps without understanding that it was a likely outcome from that strategy.

So Mike, it is likely that someone borowing an analyser to fix a problem wont obtain real benefit, but may damage it in the process.

Don't waste your time. If you download a zip file that is really a rar file,
or some other mislabled monstrosity, it's usually a scam.

Make sure your virus checker is a good one and it is up to date.

Geoff.

The first step to solving a problem is to blame someone. I prefer not
to blame hams.

Actually, I lied. Two of those that I've repaired were attached to
antennas. However, the locations are not conducive to having nearby
transmitters. One is in the deep dark forest, where the nearest
neighbor, much less nearest possible RF source, is about 1/2 mile
away. The other lives in a nearby rural area. No forest, but also no
nearby transmitters. However, it's possible that the transmitter in
question may have been one owned by the hams in question. Keying a
nearby HT or mobile might have been the culprit. Dunno.

>Roy often counseled about how his experience included many interfering
>commercial sources. And this in a rather remote reach outside
>Portland, I believe.

Attach a wattmeter to any VHF antenna on a mountain top with FM/TV
transmitters, and you'll get a watt or more of RF indicated. Nice way
to blow up the instrument.

>"No one ever expects the Spanish Inquisition!"

The Spanish Inquisition had quite a bit of support from those outside
the clergy. Much of it was about confiscating the property of alleged
heretics. When it grew in size to become a source of regular revenue,
it became an institution (much like our war on drugs). It fizzled out
when they ran out of victims.

At this point, I don't know what is causing the failures. However, I
do know what to do. Add a dummy load and buy some more diodes.

If you do not short the center conductor (on the DUT) to ground
immediately before connecting to the analyzer you risk discharging a
large "capacitor" directly into the instrument. If I am at an antenna
farm I am grounding all my test gear prior to putting it into service.
There is a Ground lug on the 259B right next to the SO239. They
provide a Type N adaptor with a new meter, too, BTW.

MFJ isn't the only ones that can suffer at the hands of others.

I was trying to locate some interference using a UHF Yagi and
a Motorola R2018 service monitor. Do not key up a hand held in
front of the antenna. At least Motorola anticipated that, and
it took out the picofuse behind the antenna connector instead
of the front end mixer.

Good point except that none of the 3 analyzers that failed were
(allegedly) attached to equipment. They were attached to antennas.
Antennas normally do not have BFC's (big fat capacitors) attached, but
do build up static charges. With the humidity currently at 60% or
more, I don't think that's likely. Also, any antenna design, that
would fry an analyzer, might also fry a radio front end. It's
possible, but unlikely.

I carry a neon lamp line tester in my tool box. It's useful for
checking AC power, but also for detecting high voltages on antenna
terminals. It's amazing what I find at broadcast sites.

The plot thickens. I checked the accuracy of the MFJ-269 and is was
off on the real part of anything it was measuring about +10%. A good
50 ohm load would read about 56 ohms. It didn't take long to find the
culprit. Instead of 51.1 ohms (1%), R88 showed 54 ohms, while R85 and
R86 read 52 ohms (or there about within the limits of my cheapo
ohms-guesser). It therefore seems possible that the owner had
transmitted into the instrument (even though he denies it). That also
might explain how 3 out of 4 diodes were found fused open. Most
diodes I've seen end up shorted when the junction is punctured. I'll
be replacing all the 51.1 ohm resistors.

Meanwhile, I added a grounded load cap, returned the instrument to its
owner, extorted a free lunch, applied the requisite instrument safety
lecture, and warned him of the accuracy problem. The dip in the VSWR
curve is all he needs at this time, which is unaffected by bridge
imbalance.

Well, do the math. The front end of the service monitor is 50 ohms.
The fuse is probably 0.1A. Power to blow the fuse is:
P = I^2 * R = 0.1^2 * 50 = 0.5 watts = +27dBm
I'll guess a 10dBi yagi and a 3 watt (+35dBm) HT into a 0dBi rubber
ducky.

[Q]: How close to the antenna can you use the HT before you blow the
fuse?

Go thee unto:
<http://www.terabeam.com/support/calculations/som.php>
and inscribe the tx power (in dBm) and the antenna gains into the
boxes. Use 0dB for coax losses and 440MHz for the frequency. Don't
worry about RX sensitivity. Plug in different values of distance
(miles) until you get an RX signal level of +27dBm. I get:
0.0003 miles = 1.6 ft

So, stay at least 1.6 ft away from your antenna and you won't blow the
fuse. Please change my guesswork to match reality and recalculate.

Drivel: Yes, I know we're close to the near field and the numbers
aren't very accurate.

>Jeff-1.0

Jeff 2.0 (the upgraded version).

I don't suppose the reference to a "picofuse" is literal to amperage
(pA), but the introduction of a 0.1A fuse is equally a supposition (I
suppose, because from my experience with precision power measurement
equipment, they often used a commercially available, specialty fuse
rated at 10mA - a Wollaston wire).

>Power to blow the fuse is:
> P = I^2 * R = 0.1^2 * 50 = 0.5 watts = +27dBm
P = I^2 * R = 0.01^2 * 50 = 0.005 watts

Getting too close (less than 5 to 10 wavelengths, and for "gain"
antennas, 20 wavelengths or more) negates directivity.

>Go thee unto:
><http://www.terabeam.com/support/calculations/som.php>
...

Actually, humidity doesn't affect the charging all that much. What humidity affects is the leakage current across dirty insulators. P-static is a nice example of static charging in rain at 100% humidity, for instance.

It's true that dry dust or blowing snow are more notorious for charging, but just the clear sky current could provide some charging.

Also, any antenna design, that
> would fry an analyzer, might also fry a radio front end. It's

I don't know about that. A LNA with a FET front end might be an example of a ESD sensitive thing, but for HF, where we're usually more concerned about instantaneous dynamic range and strong signal handling, a more robust front end is common. One of those +20dBm LO mixers, for instance, is going to be quite robust.

I can think of a lot of antennas that won't be too hard on a radio front end that would cook a delicate detector diode hooked directly up to the antenna.

There's a whole literature on making neon lamp blinkers with an antenna
and a ground.

There is a earth-sky current in the femtoamperes per cmï¿½ that has a
constant potential gradient on the order of 600V/m (or something like
that). This current is the return path for all lightning strike
charge transfers, world-wide.

Few dipoles are co-planar, parallel wrt ground.

>Actually, humidity doesn't affect the charging all that much. What
>humidity affects is the leakage current across dirty insulators.

Which could easily overwhelm this femtoampere charge where a gigaOhm
leakage is trivial (zealous Hams using teflon technology?).

Actually measuring this current (ca 1970s) required using two
polonium-210 coated probes (what are still available as static brushes
for vinyl records) feeding FETs.

The following link:
http://www.angelfire.com/electronic/cwillis/rad/brush.html
illustrates what the brush is like, and its electrical attributes.
Another source, the manufacturer (which deeply hides the polonium
reference):

It is a good lesson, (be wary) and I think that MFJ makes another "analyzer", the 207, which will suit the average user just fine, as long as they are not needing V/UHF. It's cheap, simple, small, and I used one before I got into HF mobile. It doesn't show anything but SWR. Given that that is what most people are interested in, it suits well.

Then after a bit of reading, and talking they might start to look for the interesting details, and the instruments to measure those details.

Absolutely, if acquiring an MFJ259B or the like is a stimulus to learn more of impedance, transmission lines and antennas, that is great.

Good question. I asked the same question when we discovered that the radio clubs Kenwood something HF transceiver had most of the components in the receiver front end vaporized or incinerated after a contest weekend. My best guess(tm) is that someone plugged one of the tangled mess of coax cables lurking behind the bench, into a live transmitter, thinking it was an antenna cable. Few of cables are labeled. Of course, nobody will admit to doing it.

My guess(tm) is that something like that happened with the MFJ.

Incidentally, in the box with the MFJ-269 was an N-male to UHF-female adapter, which brings back the possibility of an ESD discharge when the center pin was connected first.

Well, an admission of guilt would certainly be handy. Before anything
can be repaired, a suitable culprit must be found or assigned. Nothing
can be repaired without first establishing the blame.

If the owner confesses to gross negligence, the repair can proceed
normally. However, if he refuses to accept the blame, someone else
must be found. That's often difficult as one should not blame the
person doing the repairs. It is sometimes convenient to loan the
instrument to a fellow ham, and then blame them for blowing it up. As
a last resort, inflicting inquisition style torture on the owner will
eventually extract a confession, although subsequently getting paid
for the repair might be difficult.

Well, what I've noticed is that when the humidity is low, I throw
lightning bolts when I walk across the carpet or slide across the car
seat. When the humidity is higher, then I don't have those problems.
I don't know how this correlates to charge buildup on an antenna, but
my guess(tm) is that there would be some connection.

In a past life, I helped design a marine HF xceiver, which had a +7dBm
mixer (SBL-1) in the front end. Between the antenna and the mixer,
was a low pass filter with no capacitors to ground. There were a few
failures, most of which were due to nearby lightning hits. However
some of these failures were blamed on static buildup.

The higher level mixers will certainly survive a bigger blast through
the antenna. But that's because there's a torroidal isolation
transformer between the antenna and the diode ring. See typical
+23dBm mixer at:
<http://www.minicircuits.com/pdfs/RAY-1+.pdf>
Also note that the maximum RF power is 350mw, which is well within the
range of what can be delivered by a good solid ESD blast via the
antenna. I don't think it will fry the diodes, but might blow the
tiny wire used in the torroids into a fuse.

>I can think of a lot of antennas that won't be too hard on a radio front

Ok. I'll admit that the MJF-269 diodes, which are directly connected
to the antenna terminal, are more easily fried than a receiver front
end, which has a mess of circuitry, and possibly an antenna coupler,
between the antenna and the front end.

These days, it's called "energy scavenging" or "RF energy harvesting".
<http://www.eweekeurope.co.uk/news/scavenging-free-green-power-from-radio-waves-35622>
I used to have a 4 watt fluorescent lamp on top of my mobile antenna
that flickered with the transmitted envelope.

Oh.. that's an easy mistake to make. Bunch of coax with connectors lying on the floor, hook up the wrong one. Hook a switch up incorrectly. Coax switch without enough isolation (100W transmitter with a 20dB isolation switch is a watt into the analyzer..)

Anyone who has never accidentally cooked a piece of test equipment just hasn't been working long enough.

"Experience is directly proportional to equipment destroyed."

I think I blew up my first piece of test gear at the age of 14 or
so... tried to measure line voltage, with the VOM control still set on
"ohms". POP!

Fortunately it was just one resistor... I eventually replaced it, and
I still have that old 1000 ohm/volt VOM (a 1965-vintage Lafayette)
sitting in a drawer somewhere.

Well.. Consider a 20 meter long wire hanging 10 meters above the ground (half a 80m dipole) so now you're talking tens of pA, 100 Meg isolation isn't hard to get with clean insulators. That 20 m wire is like a 850 pF capacitor. If assume, say, 25 pA charging current, you get a volt every 42 seconds. After half an hour or so, you're up to 40 volts or so..

Granted it's not a lot of Joules.. (heck, probably not even a microjoule)..

So fair weather charging isn't likely to kill your MFJ..

Back to the dust/rain/induction charging, which can certainly get the levels needed.

It has to do with the leakage currents discharging you when it's more
humid. Interestingly, humid air has a higher breakdown field than dry air.

And, you can take ESD hits that degrade, but don't destroy, the part.
I've got some LNAs in my desk drawer that appear to work just fine,
except the NF is a bit higher than it used to be.

How do you know it was ESD that caused the degradation?

I've observed clear-air charge on a TV antenna (about 30' above ground
level) which was sufficient to create a visible spark when I touched
the center connector of the coax to a grounded static-drain block.

No rain at the time, no appreciable amount of dust (SF Bay area)...
just clear air with a mild breeze.

Oh, no, by no means - that was just my *first* time.

As in your case, the fuses tend to save most of my VOM/DVM foulups
these days. Reminds me, I've gotta go grab some 250 mA mini-fuses to
fix one of my meters and restock my oops box.

To paraphrase Foghorn Leghorn, "Fortunately, I always keep a spare set of
feathers in my locker, for just such an occasion."

I thought so. :-)

For those that weren't there (almost the entire world), Dave and I grew up in Philly and had mutual friends.

It must of been either the summer of '70 or '71, someone gave me a huge spool of teflon coated #20 copper wire (worth a fortune but we did not know that) and someone else gave me a working pinball machine.

They both ended up in another friend's bedroom and with a box, some switches and push bottons, we ended up with the world's first and possibly only voice accuated pinball machine.

The reality of it all was Dave was under a bed next to the machine, pushing buttons and flipping switches.

I remember one "mark" who would not believe that it wasn't real, even when we moved the bed, Dave popped out and showed him the box. :-)

Geoff.

Oh.. I don't know on the ones in the drawer that's what did it (because they still work, after a fashion), but on some other ones where we did failure analysis, you can see the damage on the SEM photos.

We've got whole books full of pictures of this kind of thing.

That's partly why industry has gone from marking just sensitive things to marking everything ESD, including nuts and bolts. It's just too easy to get damage without any obvious signs. Consistent practices reduce the possibility, which increases yield. The concern is the "weakening" or "partial damage without causing outright failure" kind of scenario, especially in a hi-rel situation.

There's a lot of interest in figuring out a way to test for this kind of thing, as you can imagine.

And there's even evidence that the damage can heal (anneal), much like radiation damage (both are basically deposition of energy in the wrong place and the wrong time, right), but the mechanics of the process is poorly understood.

There could actually be a fair amount of particulates without you being aware of it. I used to work for a company that made things that created fine particles in air and we tried to remove the particles as well (often using electrostatic techniques).

For very small particles, they don't scatter the light very well so you don't see them. Ultimately, you get small enough: molecule sized and you get blue sky, but even fairly large particles (on the order of a wavelength of light in size) are basically invisible as such, but do increase the attenuation, and do scatter some light so you get decreasing visual contrast at long distances (called atmospheric perspective in the computer graphics biz) One way that cinematographers can make a room seem bigger is by putting a very small amount of haze into the room, because that makes distant things less contrasty, which your brain turns into "farther away".

Some numbers:

At 1 mg/cubic meter of 1 micron diameter particles, you won't see any noticeable haziness. That's about 2E15 particles per cubic meter, and each one can have a max charge of about 1E-13 coulomb. So you can potentially move 200 coulombs with a cubic meter of air. That gentle zephyr blowing by at 1 m/sec can move a lot of cubic meters in a fairly short time. Say you have a 1cm diameter antenna element.. it will intercept 0.01 cubic meters/sec of that breeze.. 2 Coulombs/sec -> 2 Amperes...

In reality, of course, the particles won't have that much charge (they'll repel each other, for one thing), and not all of the particles will touch your antenna, especially once it starts to charge, and so forth. When I was working with a Vollrath Electrostatic Charging scheme (like a Van de Graaff generator using dust instead of a belt) the best kind of charging current I got was 10-100 microamps with dust flowing in a 4" diameter pipe at several meters/sec.

But, the real thing is that you can get particulate charging in what seems to be perfectly clear air.

Compressed air system run into this kind of thing... you can have fine oil particles from the compressor, or condensed water particles from a sudden expansion of the compressed air, both of which might be invisible, but which can build up a surprising charge.

Yeah.. the guy or gal who figures out a good non-destructive, no
disassembly required way to detect latent ESD damage is going to be a
hero for those of us building one-off high-rel gear. There have been
some partial solutions for specific parts, but no generalized way, yet.

That's easy. Because there's no emission designator for FCC approved
TDMA mobile/HT for ham radio. The ARRL is working on the problem.
<http://www.arrl.org/news/arrl-files-em-petition-em-em-request-for-temporary-waiver-em-wit
h-fcc-regarding-vhf-voice-and-data-e>
Multiple time slot systems, such as DStar are currently approved. This
is nothing new. Just approval for P25 radios.

>You could build a very nice full duplex repeater on a single
>frequency that way.

Yes, except that the ARRL has decided to only petition for a waver for
single time slot TDMA, which can't be used for a repeater.

You're scheme would certainly work, and I too am wondering why nobody
has bothered to do it. Possibly because nobody really wants full
duplex (with echo, reverb, feedback, etc).

>Sure it's totally incompatible with current FM
>repeaters, but then, D-star isn't totally compatible either. D-star and
>it's ilk are sort of half measures in that sense.

Dstar duz 5 independent simultaneous conversations through the
repeater. That's not what I would call a half measure.

>No filtering, much less intermod issues in multi station at onee site
>systems... all kinds of good comes of it.

Yep.

>Digital schemes on HF to replace SSB I can see having real trouble (the
>biggest is the lack of a "party line" capability, the other is the long
>propagation delay on HF paths), but on VHF and up FM, you already have a
>"one person talks at a time" by virtue of the standard FM demodulator.

Yep. We did that with Amtor (Sitor) for data. The big problem was
getting the switching time between T/R to less than the prop delay. If
you increase the time slicing to where it could handle voice (about
200Hz) but not be audible, the occupied bandwidth increases
unacceptably wide for HF. It's possible to decrease the switching
time, but then the latency (delay) increases to unacceptable levels. I
don't think anyone really wants a repeater with a 1 second audio delay
(even though they exist).

While not adding to your solution I saw this posting and had to put in
a plug for my simplification.

I made a simplification to Joe's beam and want to let others know.

Instead of paying for those hose clamps, I simply use a short piece
of the tubing to hold the tape. It takes a little Dremel grinding to
remove the step inside, but makes a nice, clean design with the hair-
pin match inside.

Matching, perhaps not so much, HOWEVER, the antenna pattern/phase/
characteristics are *THE* most important aspect of a DF antenna/
system. The DF antenna characteristics must be as close to ideal as
possible. I've been involved in DF since my stint in the Navy and they
went to great lengths to get the antenna sites ideal, for that reason.
Also...

But why I re-posted.... Thanks to Richard's post...
I forgot to mention a bead choke that I used with success on one of
these beams.
They also significantly improved the performance of a four dipole
Doppler type DF antenna
that one of the locals had and knew it was not right, but couldn't
decide what to do to fix it..

We used two cores on the coax to get well above the coax 50 ohms.

The following cores will fit inside the PVC pipe and around RG-58 size
coax.

Mouser: 623-2643540002
Fair-Rite (Mfr) # 2643540002
O.D. 0.562"
I.D. 0.25"
Len. 1.125
250 ohms @ 100MHz. [specs. I did not measure them as I recall]
171 ohms @ 25 MHz.

Finally,

Helmut,
You have quite a bit of reading there with that sliding element.
Can't wait to dig into it.

73, Steve, K9DCI Haven't read this group in ages.

Uhhh. It's been a long time since I worked on such a system (1975 I
think),
but IIR the prop delay through space for moderate distances kills the
idea.
Rough calculations gives a round trip delay, at 10 miles from the
repeater,
of about 0.1 ms. For two stations at that distance that's 0.1 ms not
available for sampling, bit width and processing. Keeping the BW down
also needs
rise and fall time as well as guard times. It added up quiclky back
then.
The vocoder becomes very important to reduce the data rate.

Hope I got that right...

I wonder whether you may not also have to be really careful with your transceiver/receiver switching design. You'll really need to be able to trust (and drive) those PIN diodes properly... goof up on even a single time-slice and you could put enough TX power into your receiver to turn its front end into a pile of smouldering char in a millisecond.

This isn't a problem with normal split-frequency repeaters, thanks to the isolation in the duplexer cans.

Do any of the commercial TDMA systems use the same frequencies for base->mobile and mobile->base? My recollection is that TDMA cellphone systems operate with split uplink/downlink frequencies.

>>No filtering, much less intermod issues in multi station at onee site

But "no filtering" comes with its own set of concerns.

That was 1975. The only people who ever were exposed to any propigation delay where those rich enough to make a long distance call that was routed over satellite. If I remember correctly it was about $5 a minute to call New York from L.A.

This is 2011, everyone is used the the propigation delay of digital telephones, and VoIP. 150ms is tollerable.

Looks good.

I always wonder from where you people get the PVC tubes.
My local construction markets don't.

Since you have it, can you try to make the center elements movable,
this should work with the PVC tubes also.

For you, perhaps. I have a mild learning disability and I can't use the
phone if there's too much hesi.....tation. I have a twisted pair
that connects directly to an EOC at the push of a button. SMS works
great for me.

What's really funny is "music on hold" via mobile voice circuit.

I remember frying a scope once measuring audio from a distant studio
that was on the opposite mains leg. It was a 50 cents a pound government
surplus scope, not my 465.

I would never leave an unterminated transmission line connected to my
transmitter. You always want 50 Ohms on that line when connected to
your XMTR.

I also would never "guess", (which is a kind of "assume"), unless I
really had to. I know I learned this the hard way.

I am trying to use HFTA (from the 20th Edition Antenna Book) and am a little confused in the MicroDEM stage. I downloaded two DEM.gz files and placed them in C:\mapdata\DEMs\xxxxx.gz and yyyyy.gz. (I need two files because I am located near a boundary.) Should these gz files be expanded before using? How?

The MicroDEM setup instructions (page 31) say to click on the "Weapons fan" icon. I do not see this icon on the MICRODEM 7.0 window. Also, at this point, should I be seeing a map?

I am a little confused about the next step.

Been there, blown up enough diodes to make me want to go back to
relays. However, that was about 1975, when AMTOR and SITOR were the
next big thing. High speed reliable RTTY at umm.... 3 characters per
second.
<http://en.wikipedia.org/wiki/SITOR>
At the time, everyone was trying to do SITOR-FEC and ARQ mode using
existing HF radios, including my employer, Intech. Few of our radios
were really very good at fast TX/RX switching. The basic spec was
that it had to be less than the flight time from West to East coast.
Speed-o-light is 186,000 miles per second, or 186 miles per
millisecond, or 16msec from coast to coast. That actual turn-around
spec was something like 35msec as I vaguely recall. I was thrilled
that the synthesizer PLL would settle down in maybe 25msec, and the
T/R relay in maybe 20msec. Suffice to say that some major reword was
required to get the timing correct, during which I sacrificed my share
of fried PIN diodes. Then, we dragged it out for a field test
(parking lot test), and found that the high Q antenna coupler stored
just enough energy to vaporize an ocassional PIN diode. I got fed up
with expensive Unitrode PIN diodes and substituted cheap 1N4007 power
diodes, which were far more rugged, and lived with the slight increase
in loss.

>This isn't a problem with normal split-frequency repeaters, thanks to
>the isolation in the duplexer cans.

True. However, expensive duplexers are a problem with the very narrow
TX/RX frequency offset found on 2m, 6m, and 10m repeaters. It's

fairly easy on 440 and 1215Mhz repeaters, which have wider offsets.

>Do any of the commercial TDMA systems use the same frequencies for
>base->mobile and mobile->base? My recollection is that TDMA cellphone
>systems operate with split uplink/downlink frequencies.

TDMA is IS-54/136, which is always on split frequencies. There was an HF system in Africa that I worked on in about 1979, that used single slot audio compression, and a single channel. It's idea of time slicing was trivial with a 50% duty cycle, and one cycle every 128 stolen for control. Absolutely nothing was standardized, but was very suitable for use on HF. I suppose it would be easy enough to take one of the HF digital encoders, add a synchronous t/r switch, and you have a workable start. I think this is close, but without full duplex: <http://www.aorusa.com/others/ard9800.html>

>But "no filtering" comes with its own set of concerns.

Yep. If the repeater is going in any of the buildings where I have equipement, it will need a cavity and ferrite isolator to prevent intermod problems. I know of one building that demands Heliax, no braided coax including LMR-xxx coax, all silver plated connectors, and other draconian anti-intermod measures. Tempest like packaging on all computahs. All I can say is that it works (if you can afford it).

2303. Losses in shunt-fed towers

Newsgroup: rec.radio.amateur.antenna
Date: 2011-09-09 19:10:08 UTC
From: Antonio Vernucci <vernucci@tin.it>
Message-ID: <4e6a645f$0$15672$4fafbaef@reader2.news.tin.it>
Source record: 3754

For 75 and 80 meters, I use a shunt-fed tower (58 feet high, with a fairly big HF yagi on its top). The home-made tuner, placed at the tower base, has a motorized variable vacuum capacitor in series and a (properly selected) fixed capacitor in parallel. I can so remotely tune the variable capacitor across the 3500 - 3800 kHz range obtaining a perfect match to 50-ohm everywhere in the band. The antenna works fine and I receive good reports.

The only thing which worries me a bit is the very high voltage that develops at the antenna end (about 6,900 Vrms at 3.500 MHz with 2kW applied, growing to about 8,600 Vrms at 3.800 MHz). I am not sure whether such high voltage could be a source of significant losses.

To solve my doubt, I started by precisely measuring the capacitance of the tuner capacitors, and I could then easily calculate the antenna impedance at 3.500 MHz, which resulted to be (18.2 + j 656) ohm.

ABOUT CURRENT
With 2 kW applied, one can easily determine that the RF current flowing through the antenna is about 10.5A, quite higher than the 6.3A figure one would get should the antenna resistance be 50 ohm instead of 18.2 ohm. So, I must expect some more loss in the conductors due to the fairly high current.

ABOUT VOLTAGE
The 10.5 A current flowing through the big 656 ohm antenna reactance causes the antenna RF voltage to get up to 6,900 Vrms at 3.500 MHz. Touching the wire with a (well insulated) screwdriver, you would see a nice Tesla-like arc. I am wondering whether such a high voltage could constitute, by itself, a source of extra loss. Please note that the wire coming down from the tower is connected directly to the vacuum capacitor terminal, with no stand-off insulator. So, I do not see a place where power can get dissipated due to the high RFvoltage, other than perhaps in the humid air (?).

I could probably avoid this situation by changing the tap height on the tower, but I would run the risk of not being any longer able to tune across the whole 3500 - 3800 kHz band adjusting one of the two capacitors, and not both.

Any idea on whether the high RF voltage present on the antenna could cause some significant loss?

Thanks and 73

I've never seen that anywhere. Intermod is a math problem. No amount of
silver plating will fix bad coordination.

Hi Antonio,

Describe the "shunt." (I presume it is a long wire from the tuner,
standing off 10cm or so, up maybe 5 - 10 meters where it attaches to
the tower? Can I also presume that the tower goes to ground at the
base?)

>The antenna works fine and I receive good reports.

And so it would seem this would be the end of the post. But no.....

>The only thing which worries me a bit is the very high voltage that develops at
>the antenna end

End? There are at least two, and perhaps you mean the end of the
shunt at the tuner? If by "end" you mean up at the very top, then
high voltage would be expected (but worry about it would not be
expected).

By this point, there are a lot of gaps in the description (at least
for me).

>(about 6,900 Vrms at 3.500 MHz with 2kW applied, growing to
>about 8,600 Vrms at 3.800 MHz). I am not sure whether such high voltage could be
>a source of significant losses.

You worry about loss, when you receive good reports?

High voltage reveals loss in heat. Corona would be an example, but
you don't describe corona. You also don't describe heat.

>To solve my doubt, I started by precisely measuring the capacitance of the tuner
>capacitors, and I could then easily calculate the antenna impedance at 3.500
>MHz, which resulted to be (18.2 + j 656) ohm.

I think you have a sign problem. You are describing a short antenna
with inductive reactance (given the height and wavelength, very
improbable).

However, this might be the feedpoint impedance at the lower end of the
shunt - maybe, maybe not.

>ABOUT CURRENT
>With 2 kW applied, one can easily determine that the RF current flowing through
>the antenna is about 10.5A, quite higher than the 6.3A figure one would get
>should the antenna resistance be 50 ohm instead of 18.2 ohm. So, I must expect
>some more loss in the conductors due to the fairly high current.

Only in the shunt wire. Only if you are using wirewrap wire. Measure
the RESISTANCE. Multiply by CURRENT squared. You get WATTs. How
many? That is your loss. Now, if you can measure the resistance of
your tower, stand very far back because it is about to fall over from
being rusted out.

>ABOUT VOLTAGE
>The 10.5 A current flowing through the big 656 ohm antenna reactance causes the
>antenna RF voltage to get up to 6,900 Vrms at 3.500 MHz. Touching the wire with
>a (well insulated) screwdriver, you would see a nice Tesla-like arc.

With this statement, it is obvious that you are not touching the
screwdriver to the "end" of the antenna (some 15-20 meters above your
head).

Current and voltage are not uniformly equal along the length of the
antenna. Your beam at the top acting as a top hat might yield some
uniformity, but that doesn't come from simple math analysis.

Instead, what you describe is a feedpoint impedance calculation.

>Any idea on whether the high RF voltage present on the antenna could cause some
>significant loss?

You are working very hard to find a problem that isn't there.

Sounds like you've never had to deal with transmitted intermod.
Consider yourself lucky as getting rid of it is a PITA. Also, not all
intermod comes from mixing in the receiver. TX intermod is real and
preventable. The xmit cavity and ferrite isolator prevent any RF from
adjacent antennas from going down the antenna, into the power amp,
mixing there with the xmit signal, and having the power amp amplify
the intermod.

Google for "intermod suppression panel".
<http://www.google.com/search?hl=en&q=intermod+suppression+panel&um=1&ie=UTF-8&tbm=isch>
<http://www.repeater-builder.com/antenna/ant-sys-index.html>
<http://antennasystems.com/product/sinclair-PC3/PC3113.html>
<http://www.telewave.com/pricelist/impanels.html>
<http://www.sinclairtechnologies.com/catalog/group.aspx?id=32>
<http://birdtechnologies.thomasnet.com/item/components/intermodulation-suppression-panels/
81-series?>
<http://www.ferrocom.com/products.htm>
<http://www.taradios.com/IM_Supression_Panels.html>
etc...

Incidentally, my Rotomola UHF MSF-5000 repeater has *THREE* isolators,
connected in series, in addition to a band pass cavity filter. Lossy,
ugly, but clean.

Next, silver plating is not a magic fix. Getting rid of bright nickel
plated cheap connectors *is* a magic fix. I've cleaned up several
systems by simply getting rid of cheap connectors and adapters and
replacing them with silver plated brass connectors (or just brass as
in Heliax connectors).

Google for "Passive Intermod Distortion":
<http://www.amphenolrf.com/simple/PIM%20Paper.pdf>
Materials: Ferromagnetic materials

such as nickel or steel must be
eliminated from the current path due to
their non-linear characteristics. Brass
and copper alloys are generally
accepted as linear materials. Tests
have shown that nickel plate under gold
on the center contact will typically result
in a 40 to 50 dB increase in PIM.
Stainless Steel in the body will usually
give a 10-20 dB increase in PIM.

More:
<https://engineering.purdue.edu/IDEAS/PIM.html> (nice video)
In case you've seen magnets taped to coax connectors, this might
explain why.

More on PID.

An intermod study compares transmit freqs as well as input freqs.
Circulators are accepted practice. The intermod study will tell you if
you need more traps, BPF, etc. There is a lot of pseudoscience in
technology (and a comparable amount of "overkill"). By far, the worst
problem I encounter is XM radio on 2.5 gHz and ground radar from
airplanes (they like to use tower sites as benchmarks).

I have worked some of the premiere sites (Cedar Hill, Mt. Wilson, South
Mountain in Phoenix, Mt. Harvard, Senior Road in Houston, the John
Hancock building, the router room at Channel 4, etc.) and I have never
seen a blanket ban on LMR because it leaks.

It's not leakage. The problem is the plated steel wire used over the
foil wrap on the shield. The steel is non-linear and subject to PIM
(Passive Intermod) problems. The aluminum foil to steel junction can
easily become a diode if the mylar coating is penetrated. I've seen
it with LMR-400 on a lab test similar to the YouTube video that you
apparently didn't watch. The problem was bad enough that Times had to
conjure a special mutation of LMR-400 with low PIM:
<http://timesmicrowave.com/products/lmr/downloads/126-129.pdf>
I think (not sure) that the only difference is that the braid over the
foil is now aluminum.

The initial reaction of most techs is that the PIM is sufficiently low
level that it would not have an effect on receiver performance. Wrong.
In cell sites, where squeezing every dBm of sensitivity out of the
receiver is necessary to deal with perpetually marginal cell phone
handset signals, that install cryogenically cooled front ends and
tower mounted preamps to do this, can definitely see the effect. Look
at a cell site install and try to find anything other than Heliax.

"SITE MANAGEMENT EQUIPMENT INSTALLATION RULES" (sample)
<http://www.repeater-builder.com/antenna/site-stuff/radiositerules.html>
"C. All cabling from the building to tower including on the
tower to the antenna, shall consist of a minimum of 1/4 inch
jacketed corrugated copper "Heliax" type cable. Semi-rigid
"LMR-400", "LMR-600", etc. cable and non-rigid cable, such as
RG8, RG, 213, RG-214, RG8X, etc. will NOT be used as
transmission cable exiting the building."

In most cases, this has been extended to include internal coax cabling
that carry transmit RF.

Yep. However, sometime they actually have a clue. One of my friends
recently orchestrated a site cleanup and purge, emphasizing coax
cables and isolators. After the complaining, yelling, and screaming
stopped, so did the intermod. On the other foot, the county decided
to do the same things on a crowded tower that we were sharing. All
the LRM-400 came down, and was replaced by Heliax. Much of the
intermod went away, but the mixes generated in the receiver front ends
remained.

>These are the same clowns that strip a site of any and all
>hardware that isn't nailed down or currently connected to
>something.

They're probably the same clowns that steal my scope probes that I
leave plugged into the scopes at various sites.

I had a weird problem related to unused equipment. There was an
unused "smog alert" receiver at one site, connected to an external
ground plane antenna half way up the tower. It was turned off as the
system was obsolete. Someone noticed that if they unplugged the
antenna connector, some of the intermod would magically disappear. The
outside antenna was picking up RF from the tower, delivering into the
building, and the badly shielded receiver front end was re-radiating
it all over the rack. The building manager immediately instituted a
reign of terror, demanding that all unused equipment and antennas be
removed, resulting in most of the junk exiting the building and tower.
There was a slight but noticeable decrease in intermod. Oh well.

>Or throw together a "repeater" out of junk bought at the
>swap meet and nailed to a piece of plywood.

Ahem... You must have been looking at my photos. Please don't do
that. Here's our unfinished plywood APRS weather station, built on a
plywood (with ash veneer) bookshelf:
<http://802.11junk.com/jeffl/WR6AOK-WX-Station/>
The 2m bottle is not in the picture. I use screws, not nails. There
was a good (political) reason to use plywood. Also, the rack in my
living room has plywood shelves, as are the radios in my Subaru.

Cell sites are a different animal . We were talking about 2-way,
point-to-point, VHF/UHF broadcast type sites. YouTube is pretty intense.

That same diode-like effect also seems to be capable of causing the
cable to generate a nontrivial amount of broadband noise, when
energized by a sufficiently strong transmitter signal. In simplex
applications this seems not to matter, but in repeater applications it
tends to cause enough of an increase in the noise floor at the
receiver to appreciably de-sensitize the receiver.

The system I work on, was originally build with LMR-type feedlines
within the cabinet, and didn't "hear" particularly well. When the
chief hardware guru threw out all of those (well-constructed)
pigtails, and replaced them with 1/4" heliax... the problem went away
and has not returned.

Heliax is good. Double-braid shielded cable (with silver-plated
copper braid, not aluminum) seems to be almost as good.

Such is the case on USN ships of my acquaintance. If the ship buys a
commercial transceiver and throws the antenna any old place, the front
end becomes a mixer. There's a reason why (most) military gear is
pricey. It's been engineered not to do that.

Aside:
It's not always an active device that causes problems. I had one ship
that was getting massive interference on UHF comm circuits between
about 325 MHz to 399 MHz. from a radar operating around 430 MHz.
Normally not a problem. The cause was a tangled hunk of wire I
found in the field of the radar. It had been used to secure scaffolding
during the ship's previous inport period.

Every time the radar lit up that bailing wire, the resulting arcing
and sparkling generated broadband RF pulses at the radar's rep rate.

I was climbing around on the mast, looking for just something of the
sort. When I saw that wire, I actually spoke out loud to it.

I said, "Well, hello there!" True story.

It's one of several reasons we preached "Topside Housekeeping"
to our Sailors during ship visits. Leave nothing on the mast that
doesn't have to be there.

Interesting. I always hear people bragging about LMR. Are we using the
term "Heliax" generically? Is semi-flex no good too, (It's all aluminum
and brass metallically isn't it?)

Did your guru make a profit on the replacement cables? How do you know a
$15 can of Cramolin wouldn't have helped just as much?

Tinned copper braid is OK, no?

Yeah, I've seen some of that. I spent several days finding the culprit on a UHF repeater where the over the air rx sensitivity varied substantially and erratically. Watching the IF noise level, showed it going up and down with the sensitivity changes. In frustration, I grabbed a broomstick and beat on the accessible coax cables. I eventually found a length of 9913 coax that was apparently involved. I replaced it, and the noise problem disappeared. Inspecting the coax carefully, the outer jacket was slightly corroded and white dust was visible.

>> In simplex
>> applications this seems not to matter, but in repeater applications it

Yep, but the mechanism isn't obvious. All transmitters belch some level of synthesizer or oscillator noise. The notch type duplexer does a great job of getting rid of the noise in the receiver bandpass produced by the transmitter. However, when there's a diode present, the very low level tx synthesizer spurs, or other signals picked up at the antenna, mix with the tx synthesizer noise, and land on the receiver frequency. It's intermod, but instead of dealing with a collection of individual frequencies, it deals with broadband noise. The same mechanism is a problem in broadband mux, broadcast, and cellular systems.

Requiring Heliax is a good but expensive solution. Requiring Heliax on initial installation makes is somewhat less expensive.

>> Heliax is good. Double-braid shielded cable (with silver-plated
>> copper braid, not aluminum) seems to be almost as good.

Sorta. I have problems securely attaching connectors to RG-213/u. Unlike the rigid and semi-rigid cables, crimp type connectors are problematic. In addition, much of the RG-213/u floating around is NOT

silver plated, but bare copper. That will corrode, and form diodes.

I also don't like the attenuation of RG-213/u. 5.1dB/100ft at 450MHz,
while LMR-400 is 2.7dB/100ft at 450MHz.

On 11 Sep 2011 13:32:15 GMT, dave <dave@dave.dave> wrote:

A picture is worth 1000 words:
Heliax:
<http://www.google.com/search?tbm=isch&q=heliax>
LMR type coax:
<http://www.google.com/search?tbm=isch&q=LMR+coax>

I've never heard of semi-flex. Perhaps you mean semi-rigid coax,
which includes aluminum outer jacket coax as used in the CATV
industry? The coax is fine, but where it transitions to a brass or
silver plated connector, there's a problem. In general, it's a bad
idea for reducing PIM (although I use CATV coax because I'm cheap).

>Did your guru make a profit on the replacement cables?

Guru's do not stay in business very long unless they're profitable.
Even the glorified poverty style of guru has to eat.

>How do you know a
>$15 can of Cramolin wouldn't have helped just as much?

Cramolin is now DeOxit and has been reformulated.
<http://store.caig.com/s.nl/sc.2/.f>
It's a total disaster on RF connectors because it contains oleic acid,
which is great for removing oxides from electrical contacts, but
equally good at rotting off the plating from connectors over long time
periods. The reformulated DeOxit allegedly contains a different
anti-oxidant, which allegedly has the same effect.

>Tinned copper braid is OK, no?

Dunno. I never use tinned braid except for some semi-rigid microwave
coax, which is quite stiff. Most often I see tin plated braid. Since
tin is not magnetic, there's no PIM problem.

To run HRD. I'm already aware of it. People who refer to their computers
as if they were automobiles use it. I am running my ham radio station on
Puppy Linux and fldigi for control and soundcard modes. My computer is
an "Everex 2500", which is a little tiny low powered VIA C7D-based
system that WalMart tried selling back in 2008 or so. I bought one.
Microsoft wants $150 for an OS on a $150 computer. Screw that.

Did I mention that this computer idles at around 25 Watts? Less than
most notebooks?

Cramolin is still alive and well. It was and still is made in Germany,
DeOxit is made in the US, Caig used to be the US distributor of Cramolin
products, but went their own way, with a different formula.

I'm not sure which one is the one that you call "a total disaster", but
AFIK neither is to be used for anything except cleaning. Caig sells
solutions (pardon the pun) for use on connectors.

I have them because I can only buy DeOxit in small tubes off of eBay and
still get it shipped here, and that was the only way I could get fader lube,
but I have never used them.

Don't go looking it up and show me auctions of just fader lube, after I
ordered the sets, which did not show I up, I commented to the vendor
that I wanted just the fader lube and now they list it.
They also replaced the missing packages.

Geoff.

Yes... I meant "cable with a solid or near-solid outer conductor".

> Is semi-flex no good too, (It's all aluminum
>and brass metallically isn't it?)

I think that the key is avoidance of (1) contact of dissimilar metals
and (2) ferromagnetic materials. And, you want a cable where you can
get a really good electrical contact between the outer braid, and the
connector shell. I believe that solder beats crimp in this
application, since you end up with a connection which will reliably
remain gas-tight and won't oxidize. A good semi-flex would probably
be fine, I'd guess.

LMR-400 seems to be dodgy (for repeater use) over several of these
issues.

I do like it for simplex applications.

>Did your guru make a profit on the replacement cables? How do you know a
>$15 can of Cramolin wouldn't have helped just as much?

Nope... he's one of the volunteers in the repeater group. He donates
his time, we use donated materials (e.g. the heliax cable,
ex-cell-site) when possible, and any supplies the repeater needs are
bought from independent commercial suppliers (e.g. the connectors, in
this case). He was annoyed at having to go to the trouble of
replacing the existing pigtails, but *very* pleased at the result...
it turned the system from a "basket of snakes" into one in which the
three repeaters in the cabinet can all operate simultaneously and
independently without any cross-band interference that we can detect
in any way.

We're also sharing the hospital-roof site with at least one cellphone
system, one pager transmitter (for several years - gone now), and
several public-safety LMR repeaters... and so doing things carefully
is quite important!

Both sets of cables (the original LMR and the replacement hardline)
had high-quality commercial-grade connectors... no cheap nickel-plated
imports. Hence, I do think it's accurate to ascribe the difference in
performance to the cable itself.

Cramolin is nice stuff for dealing with connector-to-connector contact
issues, but it doesn't do a thing for problems internal to the cable.

Yeah, you have to make sure you're getting the "good stuff", with
silver-plated copper braid... and then (I think) solder, rather
than crimp.

See http://www.isoconnector.com/cableassemblies.html - "semi-rigid"
and "semi-flex" are different constructions.

>Cramolin is now DeOxit and has been reformulated.

Well, sorta and sorta not. Cramolin is still made by the original
(German) manufacturer, but isn't easily acquired in the U.S. DeOxIt
is made by Caig, who used to import Cramolin but are now making a
similar product themselves.

>It's a total disaster on RF connectors because it contains oleic acid,
>which is great for removing oxides from electrical contacts, but
>equally good at rotting off the plating from connectors over long time

My recollection is that the instructions which came with Cramolin said
that you should clean the remains of the "red" Cramolin (the oxide
remover) off of the contacts after de-oxidizing.

They made another "blue" product which was intended to provide some residual anti-re-tarnishing protection... I think it was based on palm oil.

When I use Cramolin (I still have a bit of the concentrate) or DeOxIt on contacts, I follow it with a final cleaning using isopropyl or denatured alcohol (or acetone if I'm feeling really thorough), to remove the remains of the anti-oxidant.

Got it. All I can find it DeOxit in California.
More detail:
<http://siber-sonic.com/electronics/caig.html>

>I'm not sure which one is the one that you call "a total disaster", but
>AFIK neither is to be used for anything except cleaning. Caig sells
>solutions (pardon the pun) for use on connectors.

Different stuff. Most of it is just grease to keep the connectors
from oxidizing. The total disaster was what I found on a tower where
someone had used Cramolin to clean an assortment of 7/16 DIN and N
connectors. The 7/16 DIN connectors were stainless. They turned
black and had a rough pitted surface. The N-connectors were silver on
brass. The silver was intact, but would flake off in small pieces,
exposing the underlying brass, which rapidly turned dark green.
Everything had to be replaced. I don't recall how long it took to get
to this point but I think it was at least 2-3 years.

If you Google for corrosion characteristics of oleic acid, you'll find
that it attacks steels, but is compatible with copper. Not true. Pure
oleic is compatible, but add some water and the stuff becomes
corrosive.

Oleic acid is a major component (70%?) of peanut oil. You could
probably use peanut oil mixed with some organic solvent in place of
Cramolin. (No, I haven't tried it).

I mix many of my own chemicals. Most of the tuner lube type stuff is
fairly simple. Organic solvent, ionic solvent (water soluble), oxide
remover, and some oil:

I believe on of the reasons that Caig stopped carrying it was that it is
too corrosive to put on an airplane and they wanted something UPS/FEDEX
would carry.

Ok, good thing I only use it to clean contacts and that's a drop on the end
of a q-tip or toothpick.

For me those days have passed. Between space limitations, lack of working
area, inability to order those chemicals, etc, I'm going to have to make
do with little tubes sent airmail. Luckily I don't need much and have
all I need for a long time. :-)

Geoff.

Isn't there any concern for plastic deterioration from the acetone? When I read what you wrote, I cringed, having seen acetone's effect on (some) plastics. Keeping a few four-leaf clovers on the bench?

Duh... They carry peanut oil, which is 75% oleic acid, but won't
carry Cramolin, which is 5% oleic acid. I just checked the 49 CFR
list at:
<http://www.ups.com/content/us/en/resources/ship/hazardous/download/chemical.html>
and Oleic acid isn't listed. The MSDS sheet shows slightly flamable,
but otherwise safe. My guess(tm) is the business relationship fell
apart and that the UPS/Fedex story isn't true.

Yup. My work on USN ships showed me some of that. Within a few feet of any HF transmit antennas, what they call "standing rigging," things that are mounted or attached topside, can be energized with hundreds of volts. The Navy imposes RF RADHAZ and RF BURN zones in selcted topside areas. They're always marked and sometimes cordoned off with physical barriers.

Didn't Art Bell, W6OBB, former host of Coast to Coast AM, report 300 volts on his loop antenna? Even with low current, a kiss from that voltage will make you fall out of love.

Thanks. I've been calling both types semi-rigid, which is wrong.

No clue on the oil, but my guess would be cheaper mineral oil and some
solvent to wash off any residue from Cramolin red. I've never used
(or seen) Cramolin Blue.

I use 409 cleaner, which has a pH of about 11, or ammonia window
cleaner, both of which should neutralize the acid. Acetone will make
a mess of anything plastic and really is overkill. For open frame
relays, I sometime use electroless silver to replate the contacts. I
also have a diy silver brush plating kit, which I use large contacts.

I represent the not-thinking group. I'm 68 and have been doing electronics seriously since I joined the Navy at 18. OK?

In the mid-1990's, I managed to grab a cable I thought went to an antenna. I connected it to my H-T and made a call. Well, that cable wasn't to an antenna. It went to the input of my TM-221A. ($85.00, if you're curious)

If "Being Careless" were a franchise, I'd owe the fee every year. *sigh*

Perhaps you didn't notice but several of the examples of PIM and
rotten coax induced intermod were for non-cellular systems. The
problems are much the same with any service type. If you have
moderate TX power, magnetic materials in the connectors, and sensitive
receivers, PIM might be a concern.

Also, it may not be obvious unless you've worked on a cell site, but
the state-o-de-art in radio is currently defined by cellular. The
current generation of cellular radios, pre-distorting power amps,
tower mounted amps, cryogenic front ends, steerable antennas, channel
loading, codecs, and environmental protections, are far superior to
what I've seen in commercial radio, and light years ahead of the 3rd
hand garbage commonly found in ham repeaters. Yes, cellular is
different, but it's also quite superior. If the cellular people think
they have a PIM problem, it's probably quite real.

Unfortunately, cellular can't always get everything right:

No chair... standing room only. It's part of a furniture dolly that I
use to move the two MSF5000 repeaters around the shop.
<http://www.harborfreight.com/1000-lb-capacity-movers-dolly-38970.html>
<http://802.11junk.com/jeffl/K6BJ-MSF5000/backup-repeater.jpg>
It's leaning against one side of the backup repeater. The shop also
is used for small engine repair, chemistry experiments, general
fabrication, bicycle repair, and radio repair. Bench work came to a
standstill for 2 weeks while I was waiting for chain saw parts.

It depends on what sort of thing I'm cleaning. You're correct... I
don't use acetone on anything plastic.

Depending on the plastic, either an alcohol, or a light petroleum
solvent (Stoddard solvent, naptha, etc.) is a safer "wash".

True - it's for metals-only applications.

Is that Cool-Amp (powder), or some form of liquid electroless silver?

I've made up (and use) a homebrew substitute for Cool-Amp - silver
chloride and salt, finely ground, and then rubbed in firmly. Makes a
nice, solderable surface for DIY PC boards.

<http://www.cool-amp.com/cool_amp.html>
That's silver chloride and calcium carbonate powder. $25/oz. Ouch.
I've used Cool-Amp immersion plating (it's not really electroless). It
works well for PCB and contact plating. You might find this of
interest:
<http://yarchive.net/electr/pc_board_silver_plating.html>

What I have is:
<http://www.transene.com/ag.html>
I think (not sure) it's a silver nitrate, ammonia, sodium hydroxide,
and who knows what else mix. One catch is that it has to be applied
warm, which is somewhat of a challenge. I'm sure easier to use stuff
exists, but I didn't pay much for the 1 oz bottle which seems to be
lasting forever. When I run out in about 10 years, I'll look at
alternatives.

More:

Nice, but don't use salt. Use calcium carbonate instead. Salt
(sodium chloride) might precipitate the silver out at silver chloride.

Not so much full duplex, but single frequency half duplex, with
negligible time delay (implying <100ms frame time) between Rx and Tx.

Sure.. 802.11 is half duplex on a single channel, for instance.

Lots and lots of radars have fast and reliable T/R switching at pretty
much any frequency you care to name from DC to light.

TDMA cellphone uses split bands probably because it was on top of
existing AMPS systems. There is also a frequency allocation issue (e.g.
no need for new licensing). Having separate forward and reverse bands
also helps with frequency reuse and near-far issues. I hardly think
that hams are going to carpet the country with repeaters to the extent
that cell sites do.

You don't need that big a guard time if you keep track of how far you
are from the repeater and adjust your timing appropriately (that's what
a lot of systems do, and it's what was used for coarse position finding
in the phase 1 E-911 systems). That was an ordeal in 1980s to
implement, but today, it's in the piece of cake area, at least from an
implementation complexity and hardware standpoint. There is probably off
the shelf IP for it, too.

Keeping the BW down
> also needs

Yes, but on the other hand, standard cellphones use 8kbps and while the
quality isn't great, it's good enough. Of course, that gets us into that
whole "any decent codec is tied up with licensing problems" rat's nest.

Until the RF Ground is described, You can't make any definitive
decisions, about any kind of Marconi Antenna, no matter how it is feed.
This is common problem with many, less than educated, Hams, that try and
design Antennas Systems for HF. Most of the Losses in these designs are
in the RF Ground System, and not in the Radiators. Just Say'en....
YMMV...

> YMMV...

I am not interested in knowing the overall losses and making decisions on my antenna . I am just interested to know whether someone has experience on the effect of very high voltage on the antenna terminal. And for that very purpose the ground system is not relevant.

No useful answer received so far.

The problem of this newsgroup is that people not knowing how to answer a specific question, reply to other questions, just to write something.

Hi Antonio,

Then, it would appear, after your having discarded technical points
curiously you want to be validated for thinking your antenna is lossy.

It will be hard to do that without your evidence (back of the envelope
computation does not qualify) that is contrary to everyone's
experience.

Most of the delay will not come from the flight time or mux switching.
It will come from the necessary audio compression. It won't work
without audio compression, which means that some types of
uncompressible pre-randomized data is not going to work (no big deal).
Also, the more compression, the longer the latency.

>TDMA cellphone uses split bands probably because it was on top of
>existing AMPS systems.

Yep. The problem was that TDMA (IS-54/IS-136) had to be compatible
with the then existing analog cell systems. Therefore, all early TDMA
phones had to offer analog compatibility. Digital only phones weren't
available until about 2003.

There's also little justification for making the change. It will not
double the number of available channels as some pundits have
suggested. Since the return audio now has to be sqeezed into the
previously transmit only channel, the number of users per channel is
cut in half. The result is no capacity change.

>There is also a frequency allocation issue (e.g.
>no need for new licensing). Having separate forward and reverse bands

>that hams are going to carpet the country with repeaters to the extent
>that cell sites do.

I've looked into butchering cellular handsets into something usable on
ham radio. I have internals on some of the old Motorola flip phones
and bag phones and could probably modify the firmware sufficiently to
turn it into a conventional radios. The fatal flaw was the fixed
45MHz T/R offset. There were simply too many components that would
need to be replaced in order to operate on the smaller offset
available to hams, or on simplex. In addition, it's usually fairly
easy to go down in frequency, but the phones would require going up
from the 850MHz cellular bands to the 915MHz ham band. I gave up on
the idea.

Yep. The problem was that GSM had a built in distance limit at about
35 km. Any furthur and the timing would get mangled. That was
changed with adaptive timing:
<http://en.wikipedia.org/wiki/Timing_advance>

>whole "any decent codec is tied up with licensing problems" rat's nest.

Codecs are incredibly important. A 1% increase in channel capacity
translates to adding thousands of additional users to a system. Nobody
uses fixed rate codecs these daze. The current fashion is variable
bandwidth schemes, such as EVRC, SMV, 4GV, etc (for CDMA). The
challenge is to get something that sounds decent with low latency, but
doesn't blow up with weak signals, high error rates, lousy SNR, etc.
When someone succeeds, it's immediately patented, creating the
predicable licensing mess.

Drivel: I once worked on a codec that required the receiving end to
have a library of the speakers phoneme sounds in storage. That
drastically reduced the amound of information that needed to be sent.
It would have worked and possibly sold, except that it was far too
easy to impersonate someone by simply switching phoneme libraries. It
was a fun project while it lasted.

Generally, your losses are going to be IR losses. High voltage implies
low current, and low loss.

However, when you start talking kilovolts, you might have significant
loss from corona discharge.

Yes, that seems reasonable, but what conductor is that 10 amps flowing
in? What is its AC resistance at 3 MHz?

> in the humid air (?).

Corona is definitely a source of loss. Humidity doesn't change corona
much, but does change leakage across insulators (i.e. the crackling one
hears under HV power lines on damp mornings).

However, is it a *significant* source of loss? How much stuff is at the
HV? What's the actual surface field? (Running a screwdriver near it
perturbs the field)

>

>
> Any idea on whether the high RF voltage present on the antenna could
> cause some significant loss?

HV loss is hard to estimate. You could make your shunt wire a shunt
tube or rod and basically eliminate corona (A rule of thumb is that
10-15 kV/cm radius will have virtually no corona.. so for your 6kV, a
1cm diameter tube is in the right ballpark) Skin depth at 3.5 MHz in
Aluminum is .043mm, and the usual rule of thumb is to make the tubing
wall thickness 3-5 skin depths. 0.12-0.20 mm seems about right. Copper
could be thinner wall (skin depth is less)

I'd worry more about loss across dirty insulators.
And even more about IR losses.

Hello Tony,

It is not the voltage that will introduce loss (as the field lines will go into air and frequency is low), but it is (corona) discharge. Whether this occurs, depends on presence of sharp edges and especially sharp (double curved) surfaces with small radius, think of bolts, threaded rods, etc that point away from the tower into the air.

A thin end of an antenne element can also cause breakdown as it points far into the air (away from other solid structures) and the voltage maximum will be at the elements of your HF antenna.

In case of your > 8 kVrms (that is 12 kVp), an antenna element with 10mm diameter and spherical (smooth) end may result in 2.4kVp/mm at the end. If the end of the element is just straight (just cut aluminium), you will exceed 3kVp/mm and corona will occur.

If (corona) discharge occurs, you will notice a sudden change in VSWR with increasing power.

I presume that the corona effect should be visible at dark. So far I have seen none, but we had not a single day of rain since I mounted this antenna (incredible summer season...). So, I must verify when rain will come, in a few days from now they say. Or do you think that corona may not be visible?

I am using a 4-mm diameter wire so, if I will really have corona problems, I could insert the (vertical) wire into a 1-cm aluminum tube connected at the very bottom of the wire (i.e. at the antenna feed point). Probably a 2-meter long tube could be sufficient (RF voltage gradually diminishes getting away from the antenna feed point).

Hi Wim,

despite my wire is only 4mm in diameter, SWR does not vary at all applying a steady full-power carrier (not even some small oscillations of the reflected power meter needle). I then presume that no big corona effect takes place (also because I see no corona light at dark). I am not sure whether a light corona effect (i.e neither visible nor influencing SWR) could take place, but if so I presume loss would anyway be very low.

I will check again under rain conditions (test not done so far), but I am not sure whether rain increases susceptibility to corona, with respect to hot summer days (with umidity close to 80% sometimes). Any idea at that regard?

Oddly, I have been looking for a simple streaming audio app (to bring back audio from remote receivers via 802.11 for a antenna measurement project)... This one is clearly not it, but what else is out there.

Nope.. you can't usually see the corona discharge. The professionals
use a special camera with a narrow band solar blind filter.

I would think the losses as a result of 10 amperes current at the feed point not to be excessive unless your shunt feed is made of small wire. This is usually not the case if only designed for sound mechanical integrity.

Jimmie

Please forgive me but it seems a little odd that someone who can make the calculations you have made can not compute the IR losses in the feed. You are almost there.

Hello, all. I came across an article in one of my science mags in which some researchers had discovered a method to coax more bandwidth out of a given portion of the EM spectrum by "twisting" radio waves together. Nothing more technical than that in the article. Well, I managed to find one the author's papers on the subject online:

http://arxiv.org/pdf/1107.2348v2

If this technique is viable, I'm wondering why it is only now being contemplated. Note the "twisted parabolic antenna" (Fig. 3A) on p.16. Of course this makes me want to do some experiments in the ham bands. (I hope this doesn't turn out to be another CFA-like pursuit).
Sincerely, and 73s from N4GGO,

Hi Jimmie,

I am not sure of what you mean to say.

With regard to the IR loss (by the way, I presume that "IR" means I squared times R), there is little difficulty to estimate them once you know the RF current.

But my point was to estimate any extra losses caused by the very high voltage that develops at the antenna terminal. I would not know how to estimate those.

73

Tony I0JX

Please forgive me but it seems a little odd that someone who can make the calculations you have made can not compute the IR losses in the feed. You are almost there.

That is interesting.

But I presume that, increasing voltage, at a certain point the corona effect becomes visible.

Skype. It's commonly used to deliver the audio portion of HRD (Ham
Radio Deluxe). Install the remote end with your favorite operating
system and set Skype to auto-answer any incoming calls from your
account. As soon as you connect, you get audio, with fairly low
latency.

If you want to roll your own, there's:
<http://www.speakfreely.org>

There's also:
<http://umediaserver.net/umediaserver/download.html>
There are plenty of other streaming audio apps available. However, be
careful as many of them are designed for streaming music or video, and
therefore have enormous latency. I vaguely recall my adventure with
Microsloth Media Encoder 9 and it's 45 second delay.

If you want multiple channels of audio, better bandwidth, or have some
exotic requirements, you'll need to supply more detail.

I personally know one of the most committed researcher working on the twisted
waves.

No doubt on the theoretical background, but significant doubts about practical
applications of that technique (but that is just my opinion).

From what I know the experiment they carried out in Venice last May was not
engineered in a such a way to permit confirming times-4 multiplication of the
radio link capacity (times-2 due to the use of orthogonal polarizations, and
another times-2 due to the twisted waves), see
http://lighthouseinthesky.blogspot.com/2011/07/radio-vortices.html

Hello Tony,

As long as your wire with D=4mm is not close to other structures (say 0.25...0.5m), you will not exceed 1 kVp/mm when the wire itself is carrying 12kVp. You still have some margin before getting close to 3 kV/mm.

At ground level, influence of HF frequency on dielectric breakdown voltage of air is negligible. If the wire is coated, the diameter increases, hence reducing the E-field at the plastic-air interface.

When VSWR doesn't, change (with increasing power), the loss due to corona discharge will be minimal. Of course when you lose 10W from 2kW, you will not notice this probably. However if you get a discharge between metal and plastic insulation, the plastic will fail in the end (due to spark erosion).

conducting Droplets (rain) do reduce the breakdown voltage as it distorts the field. This introduces 'hot spots'. Unfortunately I don't have data on this.

I could imagine that moisture/water layer on the wire would introduces some loss (as you get a current through the moisture layer). But this is not due to corona effect.

It can be calculated, as you know the voltage and you can calculate the capacitance to ground (so you know the capacitive current that "leaves" the wire.

I had the same thought. Some of the math looked OK -- rather basic
statements of some things we know -- but there were some new terms that put
those little cartoon question marks in the space over my head.

Let's wait and see.

<john.wood@nrl.navy.mil> wrote:

>(I hope this doesn't turn out to be another CFA-like pursuit).

I've been hearing presentations of this stuff for 7 or 10 years now -
optical tweezers.

The "vorticity" can be seen in the graphic headed "Figures at a
glance":
http://www.nature.com/nphoton/journal/v5/n6/full/nphoton.2011.81.html?WT.ec_id=NPHOTON-201106#/f1

This is not to speculate about applications in the HF where energies
are many, many decades down from visible light. Where light is
tweezing molecules (very small ones), HF would be vastly
imperceptible. It would seem this reference, then, is gratuitous - a
form of authority inflation.

There are curious contradictions found:
"This novel radio technique allows the implementation of, at least in
principle, an infinite number of channels on one and the same
frequency, even without using polarization or dense coding
techniques."
compared with:
"Already with this setup one can obtain four physically distinct
channels on the same frequency by additionally introducing the use of
polarization, in this case independent from OAM. A further
multiplication of a factor five after the implementation of
multiplexing, yields a total of 20 channels in the same frequency."

Soooo. A special vorticity technique that does not use polarization
(even though they describe it as such) and does not use coding, can
demonstrate novel outcomes when paired with polarization and coding
(for which the outcome is fairly well established).

Why isn't this peer reviewed in EM proceedings?

Any strong laser beam will trap dust particles and pull them towards
a direction, I do not remember was it towards the light source or away
from it.
I consider that a thermal effect.

The effect is stunning when you see it the first time.
I worked as helper guy for laser shows, and we used Argon lasers
up to 30 watt output. Suddenly some bright spots aligned at the
beam and slowly moved along it. Dust particles in the air,
of a certain size.

The tweezing is similar to dielectrophoresis and is possibly, but not probably what you describe. In dielectrophoresis, a normally neutral molecule (water is such an example) still has an electrical dipole. The two ends add up to a neutral whole, but in the face of a non-linear electrical field, the dipole will align along the gradient and the neutral molecule can be electrostatically steered. It is a mechanism of fluidic separation done on a scale of what is called "a laboratory on chip." Panel assays (blood testing for one) are the goal.

Your 30W narrow beam could present a similar situation.

This, of course, has absolutely NOTHING to do with the claims of Vorticity.

The Vorticity effect relies on a similar news-flash that arrived here some months ago about simultaneous reception/transmission on the same frequency = very critical physical antenna geometries in a reflectionless environment.

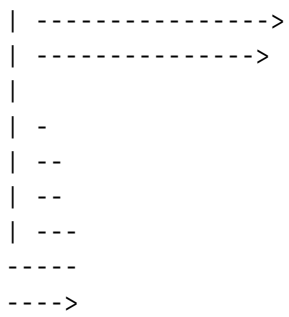
When they distort a parabol reflector, they spread the beam.
That's what the Italian clowns forgot when publishing that picture:

http://img824.imageshack.us/img824/1558/paraboldistorted.jpg

A standard parabolic reflector would deliver a nearly parallel beam
from a source at the focus point, with a certain amount
of divergence, of course.
http://en.wikipedia.org/wiki/Parabolic_reflector

Bending the parabol out of shape causes the radio waves
go into all directions and will decrease field strength at the
receiver.



Their only achievement is reduction of signal quality.
The whole thing is an absolute clownerie and a mere hogwash.

Always to the light "source". It is the prove of the wave model of
gravitation.

In the optical tweezers very small bodyies are attracted to the focus point.
After the focus the waves are diverging and works like the Sun.

Wave model of gravitation is proved in space and air.

Dear Group: I saw a note in Science News and immediately had the feeling
that it was another scam.
73, Mac N8TT

"J.B. Wood" wrote in message news:j4o4im$7kk$1@ra.nrl.navy.mil...

Hello, all. I came across an article in one of my science mags in which
some researchers had discovered a method to coax more bandwidth out of a
given portion of the EM spectrum by "twisting" radio waves together.
Nothing more technical than that in the article. Well, I managed to
find one the author's papers on the subject online:

http://arxiv.org/pdf/1107.2348v2

If this technique is viable, I'm wondering why it is only now being
contemplated. Note the "twisted parabolic antenna" (Fig. 3A) on p.16.
Of course this makes me want to do some experiments in the ham bands.
(I hope this doesn't turn out to be another CFA-like pursuit).
Sincerely, and 73s from N4GGO,

Yes.. but that's usually a LONG way from where there's detectable RFI or noise for instance. When you can see visible corona from some meters away, you're probably in the 10s or maybe low 100s of kV range.

For instance, I can run my small 14" Van deGraaff generator with no visible corona in a semi-darkened room, but, judging from the copious ozone production, there's quite a bit of corona (as well as the characteristic crackle sound).

Maybe people have seen noticeable corona at 2-3kV, but that's usually indoors in a dark room, and you're fairly close and well dark adapted. Corona from aged ignition wires (around 15-20 kV) also often visible, in the dark.

Doesn't skype not support point to point? i.e. you couldn't do it from 192.168.1.10 to 192.168.1.20 on a private network. I thought skype always needs to through the master skype resolver (to do a sort of dynamic dns function)

Install the remote end with your favorite operating

Yes, and they have all sorts of other features tailored for that kind of application.

All I was looking for was a "virtual audio cable" of some sort. (yes, I know that VAC is actually something else)

> If you want multiple channels of audio, better bandwidth, or have some
> exotic requirements, you'll need to supply more detail.

No, just that kind of simple thing.. send 3kHz BW audio from one PC to another, preferably with an app that is available for all 3 platforms (Win, Mac, *nix)

Something that has a command line like:
sendaudio -i {input audio source} -o 192.168.1.1
recvaudio -i 192.168.1.1 -o {output audio device}

would make me happy.

My antenna voltage gets up to about 12 kV peak.

I will try listening at a short wave receiver placed very close to the antenna and tuned to a vacant frequency slot. Increasing the transmitted carrier power, at the power level at which the corona effect has instated, I should note an abrupt received noise increase. .

Short note on change in VSWR due to corona.

Many reflectometers use diode rectifiers with relative heavy load. If there is no bias (or the bias is wrong), you will not notice small variations in VSWR, when VSWR = (almost) 1.

If you have a directional coupler you may use your oscilloscope or spectrum analyser as detector device. The oscilloscope (50 Ohms input impedance) you can use to verify if the residual VSWR is because of higher harmonics or real reflection. Of course the spectrum analyzer, oscilloscope with FFT or a receiver (with heavy attenuation) will show you the desired signal directly.

If you match to very low return signal, even a few Watts loss due to corona you can detect at full power. you may need to do this during very quiet weather as small mechanical changes due to elasticity of the construction materials will lead to small changes in reflection coefficient.

Simplecast.

And it's free, or used to be, if you only need 4 hours at a time. (I own a paid for copy for use in MPLS for extended emergency rebroadcasts of nets.) I and a ham in Maine used to use it to distribute the weekend "432 and Above EME Net". He had minimal bandwidth, I had enough and a Shoutcast (Icecast) server and the net was always less than 4 hours. He connected to me as the stream input and the listeners connected to my site.

Thanks to Shoutcast allowing their system to effectively be cloned they made solutions like mine possible. They even allow these systems to respond as "Shoutcast" when queried.

True. If you're not connected to the internet, Skype will not work.
The connection needs to be established via the distributed Skype
directory server system. You cannot easily bypass this to connect to
any random IP address or to your isolated LAN.

If you really want to do that, perhaps a simple G.711 VoIP client
would be sufficient.

>> If you want to roll your own, there's:
>> <http://www.speakfreely.org>

>Yes.. of course there's that "end of life announcement" from 2004.

Still works fine for me. Eventually, Microsoft will trample on some
obscure function and declare anything that then fails as legacy and
unsupported. Until that happens, it still works. Having the source
code is also very handy. SpeakFreely has been the basis of several
VoIP applications.

>I suppose that if it works well enough, one can keep using it forever
>(gosh, I've got plenty of software from the 90s that I keep using)

I'm still running a Xenix 2.3.2 server from about 1988. It should
continue to function until the hard disk quits. I've been waiting for
that to fail for at least 10 years.

>All I was looking for was a "virtual audio cable" of some sort. (yes, I

VLC will encode via an RTSP (real time streaming protocol) container
using RTP (real time transport protocol).

This looks like the magic incantations:
<http://wiki.videolan.org/Documentation:Streaming_HowTo/Command_Line_Examples#RTSP_live_st
reaming>

Server:
>> % vlc -vvv input_stream --sout
'#rtp{dst=192.168.0.12,port=1234,sdp=rtsp://server.example.org:8080/test.sdp}'

client:
>> % vlc rtsp://server.example.org:8080/test.sdp

More:
<http://wiki.videolan.org/Documentation:Streaming_HowTo/Advanced_Streaming_Using_the_Comma
nd_Line>
<http://wiki.videolan.org/Documentation:Streaming_HowTo/Command_Line_Examples>

Watch out for the screaming media features versus OS list.:
<http://www.videolan.org/streaming-features.html>

I must admit that I've never tried using VLC for encoding. If I have
time, I'll give it a try. Otherwise, good luck.

If I were to hazard a guess, this sounds like another holy grail dream for the digital folks. Many who just inherently "know" that bandwidth is infinite and can support infinite data.

Imagine - the entire universe playing Angry Birds at the same time. The mind boggles!

I have used IHU, http://ihu.sourceforge.net/ for voip streaming. It's
for Linux and that maybe disqualfies that program?

Lots of things are sold as "electric fence wire" in this part of the world.

One of them is a 2.7mm diameter aluminium wire with a HT steel core. The aluminium is sufficiently thick that it is a ver good antenna wire, it is strong and has effective RF resistance not much higher than copper.

On the other hand, we can buy HT steel wire with a flash of Zal (Zinc-Aluminium) plating coated then with polyeurathane. Makes an appalling conductor for low HF.

You will need to take the effort to better describe your own wire to get a worthwhile opinion.

Owen

It's solid and uncoated- no core. Looks like aluminum (I've worked with stainless steel wire and this wire ain't steel). Quite flexible. And the price was right. :)

I would think that if it's strong enough to hold up it's own weight
(plus a little more) then it should certainly be usable for an
antenna. Making connections to aluminum isn't exactly easy at times,
but can certainly be done. I've used the coated-steel type electric
fence wire, the hardest part about using it was the mechanical
aspects. It loves to kink. The best antenna wire is whatever you
happen to have enough of at the time, right??

"Appalling conductor"? How so? In radio school they tell us a wet piece
of rope can be used in an emergency; where does that land on the
"appalling" scale?

They sell aluminum grounding blocks at the hardware store, basically aluminum bars with screw threads every half inch or so. These are cheap and easily broken into usable splicing blocks, using a hammer and a vise.

I use these for mid-air splices on my loops, and for the radial system for my verticals. Again, remove the screws, break as needed (remember Cinch Jones barrier strips?), good DX!

I have lots of electric fence wire that is aluminum. I like it because
it's easy to handle.

However, I have never tried it for antenna wire. It is quite soft and
stretches a lot. I suspect it would be fine for a 40 meter dipole, but
for anything lower in frequency it might continue to stretch under it's
own weight, plus a center insulator, balun and coax weight.

Try a length suspended at 5-6 foot and then add some weight in the
middle to simulate the coax and other stuff and measure the sag to
ground over a week or so time period.

Missed this whn I first read it.

Seems a polyurethane coating would render the wire useless in an
electric fence use.

That is an issue for annealed copper which is probably the most popular conductor amongst hams, especially in small diameters.

One of the things that happens is that as the copper yields (stretches), it work hardens, increasing its tensile strength. So, if the forces are not too high, it might yeild a little, become a little thinner, a little longer, a little stronger and survive (for now).

At some point, the increase in tensile strength of the copper does not offset the reduction in cross section area and the stretch continues with lower tension until it breaks.

Soft aluminium wire would not seem to comply with the NEC clauses for antennas, though they are apparently widely ignored.

I collaborated on an antenna project where Gallagher XL HT steel cored 30% aluminium clad wire (2.7mm overall) was chosen for long spans in a place subject to high winds, snow and ice. It was well suited to the task, RF conductivity similar to 2mm HDC IIRC, and much stronger.

I tried 16 gauge Al wire and it was too soft & weak for anything. I
use it for bundling stuff now.
I would sure hate to depend on that to keep the bull next door!

It'll probably be okay with 50kV applied to it.

being Linux doesn't disqualify it, but having no support for other OSes sort of does..

At least it has a command line interface (useful for the remote end, which is a small Linux box) (bearing in mind the author's warning:

Those options are useful for quick launch (at least for me ;),
but I don't think it's a good idea to use them (they might be buggy),
in the future I may use standard GNU getopt, but for the moment
please use the graphic interface instead.

And it has a variety of flavors. And it might be possible to compile it to run under OS-X or windows (not in emulation or VM, but using a useful library)

The real gripe I have is that the data format isn't described anywhere (at least not that google can find). reading through the source code finds stuff about headers, stream sync, etc. but there's no obvious description of what the UDP/TCP packets look like. In fact, there's no comments in the source code, for the most part.

So if you DID want to write your own endpoint, it would be mighty tough.

It's still a math problem. You can predict intermod products from known
frequencies whether the non-linear device is active or passive.

I'm not sure what you mean with data format, but I assume you are
talking about the audio stream. IHU is just a simple interface to
Speex, http://www.speex.org/, and that is a free audio compressing
codec, at least free in the sense of BSD License.

The documentation for Speex is rather comprehensive, and it covers the
RTP format and the API.

Hmm.. Appendix C of the Speex doc does provide a RTP example. However,
IHU doesn't say anywhere that this is what it does (it does say it uses
speex for compression). It's also not clear that IHU is actually using
RTP frames. It seems that IHU has its own homegrown packet format:
(in packet.cpp)

ARCHITECTURE OF THE PACKET
*
* A IHU packet consists of 2 parts:
* 1) Header
* 2) Data
*
* THE HEADER
*
* THe header is made up of 3 parts:
*
* a) SYNC Pattern (3 bytes)
* The pattern consists of the fixed ASCII string: "IHU"
*
* b) Packet SIZE (1 byte): unsigned char that contains
* the size of the packet (min size 5, max size 256)
*
* c) INFO data (1 byte)
* It contains those informations (in order):
* - OBSOLETE: still used for bakward compatibility (versions < 0.6.x)
* Speex mode (3 bits). It can be:
* IHU_INFO_MODE_ULTRAWIDE
* IHU_INFO_MODE_WIDE
* IHU_INFO_MODE_NARROW
* - Packet type (5 bits). It can be:
* IHU_INFO_RESET 0x0
* IHU_INFO_INIT 0x1
* IHU_INFO_AUDIO 0x2
* IHU_INFO_CRYPTED_AUDIO 0x3
* IHU_INFO_KEY_REQUEST 0x4
```

```
* IHU_INFO_NEW_KEY 0x5
* IHU_INFO_ANSWER 0x6
* IHU_INFO_CLOSE 0x7
* IHU_INFO_REFUSE 0x8
* IHU_INFO_RING 0x3f
* IHU_INFO_RING_REPLY 0x3e
*
* d) Data LENGTH (1 byte): unsigned char that contains
* the size of the following DATA part (min 0, max 250)
*
* THE DATA
*
* This part of the packet is of variable size (min 0, max 250 bytes)
* and it contains the data to be trasmitted.
* It can be absent (if the packet doesn't need to transmit any data)
* or, can be audio data or keys for encpryption.
* The type of data transmitted is specified in the INFO header
*
*/
```

anyway.. the point is that while IHU probably works just fine, it's like a lot of other undocumented utilities out there: it works for what it's original author intended, and if you want to use it as a basis for software that you'd write, it's great.

However, my whole question was really to see if some simple off-the-shelf multiplatform already existed. (i.e. I'd rather spend my time doing things OTHER than writing audio transport code)

You are probably right. I've used IHU to see if Speex was good enough to use as an audiolink. I didn't scrutinize the source code. I am planning to establish a link between my noisy home (Stockholm) and my summerhouse. Anyhow that good suitable audiolink software has yet to be written ;)

Yep. And after I've done the math, I still have to get rid of the
intermod. The problem is not the math. That's well known and easy to
do. The problems are:
1. Finding which of the hundreds of signals found on a typical
mountain top is causing the problem.
2. Finding where the likely culprits are located (i.e. which
building).
3. Finding any and all sources of non-linearity that are producing
the mixes. That could be anything from a gold on nickel connector to
insufficient reverse power protection on a broadband power amp.
4. Site management and politics.

It's no longer single "known frequencies" causing the intermod. In
these days of broadband everything, it's fairly wide swaths of digital
noise that's causing the intermod. For example, CDMA phone is 1.25Mhz
wide, WCDMA is 5Mhz, and CDMA2000 is up to 25Mhz wide. The worst part
is that most of the culprits can't be decoded on my service monitor,
so I can't tell for sure if they're causing the intermod.

Sure it has. Look up SVXLINK. It was intended to link a repeater with remote sites, but you don't actually need to have a radio on either end. It has full rig control with a serial interface, although one ham here built a USB one and I believe it interfaces to commercial ones.

It has remote receiver support with voting if there is more than one, remote transmitter support and a multiuser Echolink client.

It even has the capability to be controlled via DTMF tones built in.

The SVXLINK project is an intresting one if I want to do FM and or
ECHOLINK - repeater stuff. If I just want an an audiostream then
it's i.m.h.o just to bloated with these DTMF, CTCSS .....

Bloat is relative. It's a reasonably small program that runs under Linux,
you probably could wedge it with the extras turned off onto an old router.

Gone are the days that speak freely was available, and you could run
remote audio pickups via piping the audio via ssh.

(sendprogram) | ssh computer (receiveprogam)

Worked well for me to pipe a receiver in Jerusalem via frame relay to a
remote speaker in Tel Aviv. This used 8k bits per second (plus overhead)
of a 64k bits per second line.

I don't need to sound "impressive". I have been paid to conduct many
intermod studies using proprietary software.

Cellular phones are a different animal. I worked on fixed and mobile,
mostly analog, mostly FM radios. Theory and practice are quite different.

The tower owner should have an inventory of every transmit and every
receive frequency, plus all the standard I.F., plus nearby external high
powered sources. The owner should have cleared each frequency before it
went on the air, and should not add a tenant if doing so would create a
harmful spur to existing users. This is site management 101.

I don't care how the WL people run their data streams. Cellular folks
don't like high mountains (except for backhaul). I know they use very
advanced techniques to hear signals below the noise floor; keeping that
noise floor as low as possible is of paramount importance when you are
looking at 100 mW devices in people's pockets 5 miles away.

FWIW, Tek has a real nice analyzer that will reverse engineer TDMA spurs.
make time-lapse spectrum analysis, and can even write on a map for you.

I'm curious, I'm in a marina that has an L shaped concrete parking lot
with water on the inside of the L<-- right were the arrow points.
I'm docked in the corner of the L, and want to send a signal everywhere
but the the water.
What does the pattern look like if I use a corner reflector but put
the source on the outside of the corner rather than the inside?
I'm at 433 Mhz now but may need to go to 2.4 Ghz.
The app is a driveway sensor that triggers a pocket carried receiver no
matter where I'm at on the L.
As it stands the transmitter range is not far enough, I only need 50
yards down leg of the L.

You almost made me spill my hot chocolate. You're correct. Site managers should do all that. The problem is that all but one of the site managers that I know of are business types, not engineers. They hire engineers, tower jockeys, construction crews, and generally run the business. It's not unusual for me to get a call or email with "I just signed on to have [insert name] company put their radios in the building. I'll let you know if anyone complains". This translates to "Don't burn any billable hours doing calculations until AFTER someone experiences interference. In short, I get paid to clean up the mess, not to do the planning. If I want to enforce any engineering standards, it's also done post mortem. At best, I would get an email asking where in the building and tower I would guess the new radios should be installed, usually without telling me the frequencies or equipment. Interrogating the prospective new customer is something I try to do, but often they contract out the repeater service to a comm shop, which claims that they don't know anything because they're afraid I might steal the customer. I don't wanna talk about licensing, HAAT calcs, and coordination. Hopefully, your operation is a bit closer to theory than practice.

> I don't care how the WL people run their data streams. Cellular folks
>don't like high mountains (except for backhaul).

Generally true. The CDMA crowd doesn't like high mountains for the same reason they don't like CDMA operation in airplanes. The noise floor is much higher up high and there are not enough channels available to handle all the potential users if in a metro area. However, they do like medium high mountain tops with fairly well controlled coverage areas. They also like to share site ownership and

management with public agencies to reduce costs.

>I know they use very
>advanced techniques to hear signals below the noise floor; keeping that

100mw is about the maximum that a cell phone can belch. Power control
will usually keep that down to about 30-50mw.

>FWIW, Tek has a real nice analyzer that will reverse engineer TDMA spurs.
>make time-lapse spectrum analysis, and can even write on a map for you.

Well, the 20+ year old P25 radios are finally being forced into
service by FCC edict, along with various incompatible TDMA
implementations. Meanwhile, cellular is heading towards various CDMA
spread spectrum technologies (CDMA200, WCDMA, LTE, etc), which makes
TDMA look kinda dated. Anyway, I can't afford much in the way of
expensive test equipment and usually borrow or rent what I need. I
haven't actually seen a spur, mix, intermod, or noise on a spectrum
analyzer for many years as the receiver sensitivities are well below
the analyzer noise floor. Same problem with PIM (passive intermod).
It takes quite a bit of power to produce PIM making it almost
impossible to measure PIM while the xmitters are in operation. Trying
to see PIM on a spectrum analyzer is futile.

I communicated sloppily; I mean the "theory and practice" of multiplexed
digital wireless is different than the "theory and practice" of SCPC
analog, e.g. your ability to see something meaningful on a scope.

http://www.tek.com/products/spectrum-analyzer/sa2600/

The scope is running Windows and can constantly compute intermod products
(aka predict spurs) based on the real time environment. It has an option
for advanced wireless signals. I could never get my boss to buy me one;
they are enamored of Rohde Fish 313s.

Nice. I didn't know that existed. However, the way it works isn't anything magic that can't be done with PC controlled spectrum analyzer. It also seems to have some serious limitations when looking at broadband noise (i.e. CDMA). The SA2600 looks at the display and records all the frequencies and amplitudes that it sees. It then computes the likely intermod products. This would be really cool for sites where carriers come and go (i.e. frequency hopping trunking systems, cellular handoffs, FHSS). However, I didn't see anything in the notes on how it would handle a broadband signal. If it were smart, it would measure the upper and lower frequencies of the broadband noise, and use that to predict similar broadband interference bands. However, I couldn't tell from the destructions if that's what they're doing. The box would certainly be handy for "monitoring" the receive frequency waiting for the intermod to appear. Of course the signal levels would need to be well controlled to prevent displaying mixing products in the SA front end. Much of what I see in the way of intermod would never show up on a spectrum analyzer. For example, you're not doing to see PIM on a SA.

I don't think I can justify the cost on the basis of time saved. For example, I once isolated the source of intermod to another mountain top, about 20 miles away.

Dunno, and I'm too lazy (and tired) to build an NEC2 model. I don't
think it would work the way you propose anyway.

My guess(tm) is that you want to send RF in two directions, 90 degrees
apart. That's easy. Use 2 directional antennas, such as patch or
panel antennas, and drive them with a power splitter. You'll get half
the transmit power to each antenna, but the receive sensitivity will
be the same as it would be with a single antenna (minus about 1dB for
the power divider loss).

> I'm at 433 Mhz now but may need to go to 2.4 Ghz.
>The app is a driveway sensor that triggers a pocket carried receiver no
>matter where I'm at on the L.

Ok. 433MHz has very limited range mostly because of the crappy
receivers, gutless transmitters, and miserable antennas. Improvements
to any of these will increase the range. I suggest a better antenna.

> As it stands the transmitter range is not far enough, I only need 50
>yards down leg of the L.

150 ft is difficult at 433Mhz. My cheapo La Crosse weather station is
only reliable up to about 20ft. My vehicle remote door unlocker is
good for only about 30ft. However, it is possible to buy long range
433MHz remote control switches, with much longer range. 2.4Ghz is
fine, but what are you going to use as a receiver?

Anyway, look at commercial wireless car alarms and notice that the
better variety have a small bi-directional remote, that can act as a
pager to receive alarms, and also be used as a transmitter to
enable/disable the alarm. These radios are probably better than
whatever you're using (and are probably on 900MHz). You might also
consider using a real pager and a POCSAG encoder.

I would need to purchase a pair, transmitter/receiver. Thinking about
it now, maybe I'll just get a walkie talkie set with a call button and
hack that to trigger from the driveway sensor. I did that with my PUSH
FOR SERVICE button years ago, worked fine until one of the walkie
talkies died.

At one time I hacked my cordless phone system so my PUSH FOR SERVICE button closed the call button on the base unit and signaled the cordless phone I carried in my pocket. I was never happy with the range of my phone system though. The base is inside of my boat and the boat is a double layer of aluminum, signal does get out, but I'm sure it is attenuated.
I have had thoughts about removing the RF section of the phone and putting outside, but there seems to be a lot of wires. Don't know how it would work if I stuck 25 feet of ribbon cable between the phone and it's RF section. Might be able to get that down to 15 feet.
Seems like I buy a phone system every 3 or 4 years the buttons start getting flaky from living on the salt water. (the phone, not me)
So to state the problem;
I want to sense when a customer arrives and trigger an alarm I carry in my pocket at a maximum distance of 150 feet.
If I can get the distance, I like the phone idea because I can also answer phone calls.
I would attempt to run the RF signal outside, but I have not felt I know enough about the impedance's to get a net gain after attaching coax and an external antenna. Also I've noted 900Mhz transmit and 5.1 Mhz receive, or some such scheme. That makes the antenna difficult.

Just thinking in public :-)

"Tiny Neutrinos May Have Broken Cosmic Speed Limit"
http://www.nytimes.com/2011/09/23/science/23speed.html?hpw

"the neutrinos raced from a particle accelerator at CERN outside Geneva, where they were created, to a cavern underneath Gran Sasso in Italy, a distance of about 450 miles, about 60 nanoseconds faster than it would take a light beam. That amounts to a speed greater than light by about 0.0025 percent (2.5 parts in a hundred thousand). "

I am impressed that they know the Permeability and Permittivity of that dirt path to 0.0025% at any time of year, and time of day, for any weather (for the speed of light comparison).

"Dr. Ellis noted that a similar experiment was reported by a collaboration known as Minos in 2007 on neutrinos created at Fermilab in Illinois and beamed through the Earth to the Soudan Mine in Minnesota. That group found, although with less precision, that the neutrino speeds were consistent with the speed of light."

They, obviously don't know their dirt (or it could be the effect of 10,000 lakes - umm, Italy has a lake district doesn't it?).

"Measurements of neutrinos emitted from a supernova in the Large Magellanic Cloud in 1987, moreover, suggested that their speeds differed from light by less than one part in a billion."

No dirt involved there (of course, I could be mistaken; it is a long way without a rest stop).

Michelson-Gale dicovered in 1925 that The Earth's rotation effects the speed
of light.
It becomes in agreement with SR.

So neutrinos travel with speed c and Gran Sasso with 0.3 km/s toward them.
The time to metting is shorter.

If the road is trough the Earth there no Michelson-Gale effect.

There may be the effect. But only in the time when the rotational speed is
towards to supernowa.

2438. Back yard tower advice??/

Newsgroup: rec.radio.amateur.antenna
Date: 2011-09-25 13:45:19 UTC
From: Tuuk <abra@cadabra.com>
Message-ID: <NfGfq.21160$EP3.14447@newsfe05.iad>
Source record: 3589

Hi,
I have a big self supporting tower in the yard, it is grounded by grounding rods and of course itself. I am attaching two satelite dishes to the tower. The most practical way is using 2x4 wood, this will work great just screwing them to the wood and it will squeeze itself to the brackets and support nicely. I am wondering about the connection to the tower because there will not be grounded to the tower. There wont be any connection (metal to metal) form the satelite dish and the tower, that leads me to believe that the only grounding would be the shielded cable which gets grounded to the nice new 50" plazma.

My question is should i ground that? Should the satelite dish itself be grounded to the tower? Is there any reason for this? Safety wise or interference wise? It would be very simple to do, but not sure if I should or want to. Please give me advice as to either ground the dish to tower or not to. Does anyone think there will be issues? Should I or shouldn't I?

Thanks for any advice.

Thre can never be too much grounding when it comes to lightning. You want
to bond everything together. That way any near by discharges gets grounded
and all the equipment goes up and down with the dishcharge at the same time.
Voltage does not hirt the equipment ,it is just the differance in the
voltages that does.

I think I would ground the dishes/coax to the tower and then atleast once
more just before it comes into the house. Grounding at the bottom of the
tower would also be good if the coax goes all the way to the ground.

Figures.

Several commercial tower sites I used to service used wooden
cross supports between telephone poles. The antennas were
bolted directly to the wood cross pieces.

And no, there was no grounding straps/bonds across the supports.
The only grounds the antennas saw was the "ground window" going
into the building.

The thing with lumber is that it can hold moisture and cause the tower to
rust where the wood is.
Also if it is treated wood, the chemicals may cause the same thing only
faster.

Each cross brace has about a dozen 2" diameter galvanized stubs to
attach the antennas to. They are bolted directly to the cross braces.

All the wood was treated with Creosote just like the poles themselves.
The site was at least 40 years old the last time I was up there in 2005.

The stubs didn't look any worse than the usual stubs bolted to metal
tower assemblies.

I think Creosote is mostly a form of oil. Probalby helps iron not to rust.

The newer treated wood needs special screws depending on the chemicals used.
Thank the EPA for that.

I'm not sure I'd want to hang a TVRO dish on one. Have you ever been on
the upper levels inside the Post Office building on Mt. Wilson?

You mean like this?
<http://802.11junk.com/jeffl/pics/Old%20Repeaters/slides/LoopMtn02.html>
<http://802.11junk.com/jeffl/pics/Old%20Repeaters/slides/LoopMtn03.html>
We had similar derrangements at 3-4 other sites. Telephone poles and
lumber were about 20% of the cost of a galvanized steel tower.

Lightning protection was at the entry point to the building with a
metal plate with some PolyPhasor feed through protectors. The end and
highest antennas were also grounded with a undersized #4 copper wire
running down the pole to a ground rod at the base. We didn't get any
lightning hits because there was an all metal forestry lookout at the
highest point on Santiago which took all the hits.

>The stubs didn't look any worse than the usual stubs bolted to metal
>tower assemblies.

We used the same hardware that was used the Ma Bell. Thick galvanized
and loose fitting steel hardware. Same as what the typical steel
tower is made from these days. It works nicely on both metal and
telephone poles.

>The most practical way is using 2x4 wood,

It won't work. The problem is that wood towers move. If the satellite dish just happens to have a very narrow beamwidth, such as with a point to point link or DBS dish, that movement is going to misalign the dish. I had a (non-paying) customer with such a derrangement. Instead of a steel pipe and concrete filled hole mounting as recommended, he installed it on top of a 20ft 4x4. I was asked to align the dish properly, which turned into a exercise in futility. The wood was still fairly green. Every time the sun shined on one side of the 4x4, it would contract on that side only. I bought a MEMS inclinometer and setup a laser pointer to measure the changes. My guess is about a 3 degree max change at the top. Note that the beamwidth of the common 24dBi 2.4Ghz dish is about 5 degrees, which means you have to be accurate to at least +/- 2.5 degrees.

>this will work great just screwing
>them to the wood and it will squeeze itself to the brackets and support
>nicely.

Using a piece of 2x4 as a yard arm will probably not produce as drastic a change. It will be somewhat less, but it will still be present. In addition, you'll have the never ending problem of securing the 2x4 properly with bolts. As the wood dries out, you'll be tightening the bolts, and re-tweaking the dish alignment.

>I am wondering about the connection to the tower because there will
>not be grounded to the tower. There wont be any connection (metal to metal)
>form the satelite dish and the tower, that leads me to believe that the only
>grounding would be the shielded cable which gets grounded to the nice new
>50" plazma.

OK, it's a DBS dish. The typical 18" pizza dish has a beam width of about 4 degrees. If it's a multiple LNB dish as used to get HDTV channels, about 3 degrees. That means you'll need to be accurate to about +/- 1.5 degrees. Wood won't work.

It will also be rather amusing to watch you try to align a dish to 1.5 degrees accuracy at the end of the 2x4. The usual method of pre-setting the elevation, and spinning the dish for max signal to get the azimuth will work only if the mounting pipe is absolutely vertical. That's not easy to do or adjust with a 2x4 hanging out away

from the tower.

>My question is should i ground that?

Running a heavy copper wire up the tower and across the 2x4 might be a problem. That's because of the right angle turn at the tower. Lightning doesn't like to make right angle turns and will probably jump to the tower. I don't really know if this should be a concern.

The local DBS installers just use a #10 copper wire to the nearest earth ground. The cable guys just ground the F connector at the building entry. They're not really designed to take a lightning hit, just to bleed off any static electricity that might accumulate or to deal with an indirect hit.

>Should the satelite dish itself be
>grounded to the tower? Is there any reason for this? Safety wise or
>interference wise? It would be very simple to do, but not sure if I should
>or want to. Please give me advice as to either ground the dish to tower or
>not to. Does anyone think there will be issues? Should I or shouldn't I?

Well, if you're going to go through all that trouble to install a proper ground, you can do as well using Unistrut instead of a 2x4. <http://www.unistrut.us>

The grounding inside and outside the building was your typical "Amateur"
installation. 3/4" water pipe with 90 degree elbows soldered together.

Our real protection was the water tank owned by the DWP slightly up
the hill from us. Similar to ranger tower protecting Santiago.

Yup. Works moderately well until you get some clown in the building
that runs an 8-way receive antenna and 8 bandit taxi cab repeaters.

As the other Jeff pointed out, there's reasons to NOT use wood,
but it's not because wood is bad. Purely a dimensional change
problem.

Although, I suspect that the original poster is thinking of
strapping a 2x4 across two legs of the tower and using just enough
"arm" to get the dish to clear the tower. It may work, and it may
be a nightmare trying to accurately align it.

There were plenty of telephone pole antenna "towers" in the Hollywood
Hills during the 1960's and 70's. Most are probably still there. A
steel tower required an elaborate ordeal process compliments of the
planning department. Telephone poles were deemed to be something akin
to a tree, and were easier to permit.

During the 1960's, Ken Sessions (SK) had a GE outdoor box mounted on
top of a telephone pole just below Loop Mountain. His problem wasn't
lightning hits. It was hits from .22, .38, and larger. He reinforced
the inside of the box with armor plate, which worked until someone
used AP ammunition. We offered him cheap space in Gene Clothier's
site on Loop, but Ken refused for some unknown reason.

>The grounding inside and outside the building was your typical "Amateur"

Lousy cross sectional area. Hopefully, they left one end open. If
the copper pipe were sealed at both ends, and it took a lightning hit,
the air inside would get rapidly very hot and probably turn the pipe
into a fragmentation bomb. If they really want to blow out the wall,
fill it with water.

Bowmont water tank, off Mullholland between Laurel and Coldwater
Canyons?

Of course the end wasn't open. And there was a pair of Tee's in
the middle so it could zig zag across the ceiling. There was a
second ground pipe running around the outside of the building.

Other sites had a decent ground using #4 solid copper wire and
exothermic connectors. This, obviously, was not one of them.

I don't think so. This one was off of Cyprean Dr. Via Hollywood Blvd.
<http://g.co/maps/dw5py> 2050 CYPREAN DR. LOS ANGELES, CA

If that link works properly, you can see a nice clear picture of the
antenna rack.

K-Joy site? You must know Western Technical Services if you used to play
in Orange County. They build steel towers. If you order a mesh dish they
send an unmarked vehicle.

Never heard of them, but that was 40 years ago. We did our own
antennas all of which were on wood poles. Same with everyone else on
Santiago Pk in the late 1960's. Even the Air Force building used
multiple short telephone poles, with one antenna per pole, a really
bad idea. I worked for PMC (Pacific Mobile Comm) in Stanton CA at the
time.
<http://11junk.com/jeffl/pics/Old%20Repeaters/slides/PMC02.html>

Why would they send an unmarked vehicle to install a mesh dish?

I think (not sure) that I found a recent (4/2009) photo of the PMC
building on Santiago:
<http://images.summitpost.org/original/503620.jpg>
Note the large number of wooden poles and outriggers that are still in
use. I was going to mumble something like "nobody mounts dishes on
wood poles", but it seems that there are two in the photo. Sigh. The
wood structure looks much the same as it did 40 years ago minus the
wall of far too closely spaced, intermod generating, antennas.

Recent structures are all steel.

#4 is plenty big enough for lightning grounding. The current is high,
but the duration is short. You see larger lightning conductors for
mechanical reasons (e.g. where it might get damaged, or where it has to
move repeatedly).

I think one can safely assume that the folks doing the experiment are aware of all those potential error sources.

http://arxiv.org/abs/1109.4897 has most of the details

For instance:
"The distance between the target focal point and the OPERA reference frame was precisely measured in 2010 following a dedicated geodesy campaign."

the distance is 730534.61 +/- 0.20 meters, by the way.

"The high-accuracy time-transfer GPS receiver allows to continuously monitor tiny movements of the Earthï¿½s crust, such as continental drift that shows up as a smooth variation of less than 1 cm/year, and the detection of slightly larger effects due to earthquakes. The April 2009 earthquake in the region of LNGS, in particular, produced a sudden displacement of about 7 cm, as seen in Fig. 7. All mentioned effects are within the accuracy of the baseline determination. Tidal effects are negligible as well."

The odds are distinctly against that being true.

At the end of the day, the measurement is going to expose a design
flaw (recall the Hubble Lens?), not shake the foundations of Physics.

One of the neighboring towers took a direct hit. The #6 AWG he was
using literally exploded, spraying melted copper everywhere and
blowing pieces of concrete block all over the building.

<http://en.wikipedia.org/wiki/American_wire_gauge#Table_of_AWG_wire_sizes>
Fusing current (32msec) for #4 is 34,000 Amps. The average lightning
hit is about 20,000A but can go up to 200,000A.
<http://www.lightningsafety.com/nlsi_info/media.html>
Other references offer averages from 5,000 to 50,000A. I would call
#4 marginal but probably adequate for California, which doesn't get
much lightning.

Unistrut is wonderful. About 20 years ago, I used to engineer installations
in a big government lab in San Diego and it was the customer's preferred
method for anything structural that didn't involve concrete. :-)

I learned you could do anything with Unistrut. It's the Erector Set / Lego
Blocks for grown-up kids.

Agreed. However, you have to be careful using Unistrut for outriggers
on towers. Unistrut doesn't do well when twisted (in torsion) by a
top heavy antenna. The only way that seems to work well on a tower
are two 1 1/2" channel Unistrut outriggers, with a connecting pipe for
mounting the antenna, dish, or whatever. A single outrigger usually
results in a the antenna twisting around in the wind. (1 1/4" will
work with light antennas).

Something like this:

Thanks for all the info

I am going to ground out the satellite dish to the tower.

Now it is grounded to my new plazma and I would feel more comfortable with
it grounded to the tower. Don't want nothing happening to that new plazma.
Now of course if it ever got hit by lightning I would imagine the receiver
would get fried, maybe not the tv, the coax goes into the receiver, then
into the yamaha sourround sound then into the tv. A jolt has to stop
somewhere along that line.

I know what an opto-isolator is. (Provides a signal path with a short-range modulated light beam -- no copper connection) I don't know if any have been designed/sold for lightning protection.

Anybody?

One might want to check a different source for fusing current. The standard test lightning stroke has a 2 microsecond rise time (10% to 90%) and a 50 microsecond fall time (to 50%) typically represented by a double exponential (1-exp(-t/a))*exp(-t/b), so when you used the Onderdonk equation, you want to use a 50 microsecond pulse

In general, fusing goes as a function of the "action", I^2*time.

The equation from Onderdonk is usually used for this kind of thing (as shown in the table you cited). Onderdonk's equation assumes a rectangular current pulse, but that works for the most part and for lightning, it would be a conservative estimate.

For a 50 microsecond pulse, the fusing current is 22 amps/cmil (vs .87 A/cmil for the 32 ms pulse)

AWG4 is 42kcmil, roughly, so the fusing current is well over 8000kA

Another approach to analysis might be to consider the energy dissipated in that wire. It's a bit tricky, because as the wire heats up, the resistance increases. (by a factor of 4 or 5 at the melting point, as I recall)

But let's consider a meter of that wire which is 5.189mm in diameter. it has a resistance of 0.82 milliohm (at 25C). Let's round up to 5 milliohms.

Let's say our lightning stroke has an RMS current of 50kA (peak current would be higher), so we have (50E3)^2*5E-3 = 12.5 MW. But that lasts for only 50E-6 seconds, so we deposit 12.5E6*50E-6 = 625 Joules into the meter of wire.

That wire has 21 sq mm cross section so the one meter length is about 21E-6 cubic meters or 21 cc. Copper has density about 7 g/cc, so we've got around 150 grams of copper there. At a specific heat of 0.385 J/g every 58 Joules will raise the temperature 1 degree. Since we're dumping in about 600 joules, that lightning stroke will raise the temperature around 10 degrees.

In practice, a typical lightning strike has several strokes, so you probably dump 4-6 times that amount of energy into the wire. But still, you're talking maybe a 50-60 C temperature rise, which is LONG way from the 1000 degree rise you need to melt the copper.

Your observation of total destruction of a copper conductor was probably from some other mechanism. The electromagnetic forces are the best candidate. I used to do some quarter shrinking, and a few thousand amps in sub millisecond pulse would destroy a AWG10 coil from the magnetic forces.

An unsupported turn of AWG 4 or 6 wire would probably be destroyed by a 20kA pulse with a rise time of 2 microseconds. The di/dt is 400E9 A/sec, so the flux is pretty spectacular.

The other source of disaster in high power pulse discharges is if there is a loose connection or a gap in the conductor. The several tens of volt cathode drop in an arc at 20kA gets the peak power up pretty high, and unlike in the example above where the 12MW is distributed over a meter of length, you get that megawatt dissipated in a few cm, so the energy density is much higher.

Typical optos can stand off 5kV or so. Speed is a problem There are off
the shelf opto isolator widgets for things like RS232 and phone lines
that are fairly inexpensive. Get to RF, though, and the price goes way up.

If you need more, you go to a fiber optic link of some sort.

Almost certainly you're right. But as far as the error sources
referenced in the older post (solid earth tides, etc.): those have been
taken into account.

Y'er welcome. Now, if you want a usable answer to your question, it might be helpful if you describe the tower, what manner of DBS dish, and some of the distances involved.

>I am going to ground out the satellite dish to the tower.

If your unspecified type of tower is properly grounded, the tower will protect the dish from a direct hit. Still, it's a good idea to ground everything to reduce the effects of induced currents from a nearby hit.

Grounding the dish is probably a good idea. Grounding the LNB at the dish is a bad idea. Depending on model of LNB, many of them have no DC connection between the LNB case and the dish ground. This is not for lightning protection but to prevent ground loops. In general, you want to do it the way the installation manual suggests and the NEC electrical code demands, which is a grounded barrel connector somewhere close to the utilities ground.
<http://www.dbsinstall.com/whatis/Whatisgood-5.asp>
Such a ground is NOT to protect against lightning, but to protect against getting electrocuted if the satellite receiver magically loses its protective AC ground and leaks some 117VAC onto the coax.

This discussion has some good comments on DBS dish grounding.
<http://www.dbstalk.com/showthread.php?t=16300>

>Now it is grounded to my new plazma and I would feel more comfortable with

The general idea is to give the current a better path to ground than through your expensive electronics.

Incidentally, I just found this on using wood for mounting:
<http://www.dbsinstall.com/diy/GroundPostInstallation.asp>

What's inside a Polyphaser cellular lightning protector:
<http://802.11junk.com/jeffl/pics/lightning/index.html>
Note the 4 ceramic spark gaps in series. You get 4 hits, and then it shorts out.

Recently acquired an LDG tuner. Nice part.
I'm looking forward to the not having to twist knobs every
time I change frequency.
It comes with an adapter cable for Icom radios, but it's a
4-pin Molex connector and the manual doesn't show what the
connections/signals are for the radio.
Anyone out there connect this tuner to an IC-761 already?

Thanks

Buy or clone the LDG Icom interface cable. The IC-761 supports the
Icom AH-4 antenna tuna, so it should work:

For close to 40 years I bought into the myth of 50 ohm antennas.
Absolute crap results. (Well, I've always had very good luck with
a dipole for one band.)

Earlier this year I put up a 102' doublet fed with open wire line
and have been working the entire planet with less than 100 watts.

But you're right, I'm a lazy bastard and would like the frequency
agility rather than having to tweak the knobs on the MFJ tuner
every time I change frequency.

Mythology went out with the Greeks and the Romans. Modern antenna
design requires newer beliefs and religions. Apparently, your
practices within the Cult of 50 ohms has failed to bring about the
desired miraculous DX. You might want to petition the radio gods for
a review of your design before you discard the cult completely.
However, there are alternative religions.

In my case, I switched and am now a practicing member of the Cult of
75 ohms. The difference is subtle. While worship of the 50 ohm idol
results in the maximum power transfer, the change to 75 ohms results
in minimum coax loss and somewhat easier antenna design. However, the
major benefit is it allows one to minimize the tithe paid to vendors
as CATV coax is cheap and readily available. I suggest you consider a
religious conversion.

>Earlier this year I put up a 102' doublet fed with open wire line
>and have been working the entire planet with less than 100 watts.

Hmmm... perhaps that's because the bands were miserable all last year
and have only recently begun to show signs of life. Timing is
everything.

I thought you were trying to load a barbed wire fence. I'm
dissapointed.

>But you're right,

Far right, please.

>I'm a lazy bastard and would like the frequency
>agility rather than having to tweak the knobs on the MFJ tuner
>every time I change frequency.

Yeah, I know the problem. Every time the kite at the end of your
102ft doublet looses altitude, and the middle scrapes ground, you have

to retune. However, the IC-761 has plenty of knobs and switches to play with. I don't see how a few more on the tuner could make any difference.

>Jeff-1.0

I think your question relates to the connections between the LDG and that Molex plug.

Was it LDG who supplied the adapter? If so, ask them. Seems a bit silly that would supply the thing without adequate information on how to use it.

Owen

Well, I did ask LDG and they were kind enough to send me the application note describing the connections.

And the more I looked into this the more I realized, "You have an antenna tuner built in into the Icom IC-761."

Homer Simpson moment, "Do-oh!"

However, the specified tuning range of the internal tuner is 16.7 to 150 ohms. The LDG is specified as 6 to 1000 ohms. A bit more latitude.

OK, "How did I get side tracked like this?"

Earlier this year I got an MFJ Versa Tuner to use with the doublet antenna. It works fine. But of course, it's manual. (But it does have a 4:1 balun inside.) So I get the LDG in a swap for some goodies. No balun inside. Ok, I ordered an MFJ 4:1 current balun. And those do work a LOT smoother tuning that with the internal 4:1 voltage type the MFJ tuner has.

It was while obsessing over the "talk to the radio" cable for the LDG that I realized, "Oh right, this is designed for radios that don't have internal tuners." For example, my Icom IC-726 has the correct interface to talk to the LDG. I do have the matching AT-150 auto-tuner for the IC-726. That is specified the same as the IC-761 tuner.

Once the balun gets here, the FIRST thing I'm going to do is to find out if the internal tuner has enough range to deal with my antenna.

I just love wild goose chases, because in the end, you usually do learn something useful in the process.

Well, I've come to a few conclusions.
1. Dipoles with a 1:1 balun work very well.
2. See #1. However, the trees and other things they are attached to
are hard to rotate.
3. Vertical antennas load nicely. So do Bird Termalines. And they
radiate about the same.
4. See #3. If I had room for a bunch of radials to make the vertical
work properly, I'd have room for a real antenna.
5. Yagis do nicely. _IF_ you have the tower and rotor to put them on.
6. A 102' doublet with open wire feed line and a tuner works amazing
well and considering the cost difference is flat out outstanding.

Re: #4. Having moved to a small rural town in central Texas, I have
a lot of room now living on 1/2 an acre.

I already had a used 40' tower and was given the tuner as a bribe to
try the 102' doublet. And I had a 500' spool of #14 THHN house wire
to play with.

Isn't half the fun of all this seeing what works well for you?

Yes, there is always a risk of that.

The auto tuner can be a path to hiding shortcomings in an antenna system, in search of the holy grail, low VSWR.

Whilst you seem critical of the 4:1 voltage balun in the MFJ, it is my perception that they are still the most popular balun. My theory on that is that antenna systems that exhibit extreme impedance can often be 'matched' with that configuration, assisted by the loss in the balun.

It is an example of how the device's operation can be misunderstood. There is little doubting the considerable anecdotal evidence that 4:1 voltage baluns work 'better', it is understanding what is meant by 'better' that is revealing.

That leads into the question of whether a 4:1 balun is 'better'.

If you were selling product, you would concentrate on the things that deliver good VSWR, because that is all that is in the minds of most buyers.

Owen

PS: for avoidance of doubt, nothing above should be interpreted to recommend a 4:1 voltage balun or a 4:1 balun.

This is a 102' doublet with 40' of open wire balanced feed line.
Except for the input of the tuner looking like 50 ohms to make the
transmitter happy, there is no such thing as "low VSWR" on this
type of antenna.

Actually, the MFJ 949b Versa Tuner has an internal 4:1 voltage balun.
The reason for that is simple. One large toroid and you're done. There
isn't room inside the case for a 4:1 current balun.

If you disconnect the open wire line from the internal voltage balun
in an MFJ tuner and replace it with an external current balun you will
find that the tuning of the match on the tuner is a lot smoother as
opposed to almost erratic. (But still obtainable.)

Due to the location of my station on the 2nd floor over looking a
covered porch, having a "good RF ground" is not going to happen.
The current balun forces the antenna and feed line into a truly
balanced condition. No ground needed, other than a proper bonding
of all the related equipment to a common reference in the station.

The whole purpose of the tuner is to allow the transmitter to see
a 50 ohm unbalanced load that it was designed for. Accomplishing
that, allows the most power to be transferred to the antenna. The
102' doublet with open wire line seems to do a remarkable job at
radiating. (And equally well at receiving.)

> That leads into the question of whether a 4:1 balun is 'better'.

Better than what? A 1:1 balun or none at all, which seems to be
the selling point of the G5RV antenna and it's clones.

Well to "make the transmitter happy" is jsut the new language for low VSWR.

Ok, so in your experience, you haven't yet come across a load that could be matched with the voltage balun, but not with an external current balun.

> Due to the location of my station on the 2nd floor over looking a

Ideal conditions like "forces" and "truly balanced" don't often exist in the real world. It would be of more interest if you had measured and reported the differential and common mode current at various frequencies.

> The whole purpose of the tuner is to allow the transmitter to see
> a 50 ohm unbalanced load that it was designed for. Accomplishing

Yes. It is the meaning of "most" that is relevant. Most doesn't need to mean 100%, or close to it, you make compromises for frequency agility and multiband use, but "most" is often unknown. Perhaps some DX QSL

cards can substitute.

> 102' doublet with open wire line seems to do a remarkable job at
> radiating. (And equally well at receiving.)

Yes, they can be a good antenna, but it is not a no-brainer.

For example, a correspondent recently reported problems with just such a thing on 40m. Turns out his feed line length was such that at 800W into the feed line, the voltage between the wires was some 4000+V and was causing flashovers in a 3kW rated ATU. In this case, I recommended that since he could not lengthen or shorten the feed line enough, that he shorten the antenna so solve the problem.

He had previously smoked up a CWS Bytemark 5kW rated current balun on 80m with another antenna, caused by unlucky feed line length.

>
> > That leads into the question of whether a 4:1 balun is 'better'.
>
> Better than what? A 1:1 balun or none at all,

1:1.

4:1 reduces the voltage impressed on the ATU components, which is good for high impedance loads, and poor for low impedance loads.

There is no simple thing that always works best on a random set of loads (which is the case for many multi band antennas).

> which seems to be
> the selling point of the G5RV antenna and it's clones.

Perhaps to some. There is good argument for use of a balun with a G5RV and not-balanced transmitter. Varney conceded that in one of his later articles. Most people who are adament about what Varney did or did not describe have not read his articles. Antenna manufacturers are not a good source of factual information.

You're missing the point. The "Holy Grail" is low VSWR at the antenna.
Obviously having the tuner present a nice resistive 50 ohm load to a
transmitter designed to be loaded with a resistive 50 ohm load is a
"Good thing(tm)".

But with a random length, i.e. non-resonant, antenna, VSWR at the
antenna is not a meaningful term.

>> ... There
>> isn't room inside the case for a 4:1 current balun.
>

But my point was MFJ chose to use a voltage balun for two reasons.
They're cheaper and they still work to a fashion.

> Ok, so in your experience, you haven't yet come across a load that could
> be matched with the voltage balun, but not with an external current
> balun.

Not yet. If it matches at all with one, it will match with the other.
The difference being that the current balun results in much less
erratic/sudden/critical tuning of the antenna tuner itself.

>> Due to the location of my station on the 2nd floor over looking a

Um, actually, yes they do. That's the whole point of a current mode
balun.

As an example then. How about working RA3DA in a pileup competing with
the "big guns" in New York running at or above the legal limit? Sure
I didn't get him on the first call, but I did it running under 100 watts
and into a $25 antenna.

See above. Why is it that hams seem to think they absolutely need to run
800 (or more) watts of power?

You're hear equally unsubstantiated claims about how well an off center
fed Windom antenna works with no tuner as well.

Yes. Somebody in this group (you, maybe) previously promoted 75 ohm cable.
This past spring, I was modeling my 20m Field Day dipole, varying size and
height for best pattern shape and minimum VSWR. At optimum, it had almost
exactly 75 ohm feedpoint impedance. Having plenty of TV coax, I didn't
hesitate to go with it. The antenna worked wonderfully well at FD.
Transmitter seemed to like it just fine.

Sal, you will have discovered that the feed point impedance of a half wave dipole at resonance is dependent on height above ground, type of soil etc.

This need not be a choice between 50 ohms and 75 ohms.

My 40m inverted V dipole uses 75 ohm feedline (RG6), and the impedance looking into the feedline is close to 50+j0. Dipole height was determined prior to design of the matching system (ie height was not constrained by the matching solution, rather the height set a requirement for the matching solution). The transmitter has its rated load impedance, the feedline is efficient and inexpensive. There is a W2DU style choke balun near the feedpoint, and measured common mode current is quite low.

Of course, the feedline has standing waves, and the dipole is not resonant, to be frowned upon by some (many?). The antenna system can be readily modelled, and it has higher efficiency than a resonant half wave with comparable coax (say RG8X), indistinguisable pattern, marginally higher gain.

Probably me. I tend to promote the use of 75 ohm coax and systems.
Most of the coax cables to my rooftop antenna farm are 75 ohms. The
justification was convenience and price. I obtained five 1000ft rolls
of RG6a/u mutations (some with messenger wire), and some used hard
line, and couldn't resist using it. The only problems seem to be
getting accurate readings on my test equipment and having enough
F-to-N or F-to-BNC adapters.
<http://www.qsl.net/n9zia/wireless/75_ohm_hardline.html>

Note that using 75 ohm coax on a VHF/UHF repeater is a really bad
idea. Duplexers, isolators, circulators, cavities, and such are very
sensitive to mismatch. For repeaters, use only 50 ohms.

I have an MFJ-928 ATU at the feed point of an elevated 43' vertical, with
a half dozen radials of various random lengths. It works great for
30/20/17/15. It starts making significant multiple lobes above 21 MHz.
I'm going to try a coil for 80.

What is the price differential in winding one wire outside the core,
instead of winding it inside the core? Such "savings" accrue only in
the production run of millions of units.

>and they still work to a fashion.

If both sides are unbalanced - you mean that fashion?

MFJ is not making a killing on this particular poor winding (OK, call
it historical inertia) practice, and their market for these internal
BalUns is dipoles, not monopoles.

I need to find the internal ram board for an Icom 745/751. I broke mine by pushing too hard when reinstalling.

Money is tight, as we all know. Do you have one that I can buy?

I sure would appreciate it.

Thank you.

> BalUns is dipoles, not monopoles.

Hi Richard,

I see MFJ getting mention, and whilst they may deserve a bit of a flogging for some things, I spring to their defence on this occasion.

MFJ make the claim "More hams use MFJ-949s than any other antenna tuner in the world!" and gauging from questions in online fora, they are indeed popular, the claim may be correct.

The MFJ949E uses a Ruthroff voltage balun.

I have measured the balun losses in my '949E, and they are as I discussed in the general case earlier, quite high on high impedance loads. Anyone with a rudimentary knowledge of balun design would understand that, but there are those who apparently live in an ideal who would refute it.

The simple explanation is that most loss in practical ferrite cored baluns usually results from losses in the core material. The losses in the core material are related to flux density, which in a Ruthroff voltage balun is roughly proportion to the differential voltage, and in a Guanella current balun is roughly proportional to common mode current. There is no reason to think that these two different types of baluns would have identical losses.

The MFJ949E could easily be reconfigured as a Guanella 1:1 balun by changing its end connections, but that does not make it an optimally designed current balun. I haven't done it, and so cannot comment further. I cannot see how the cost of manufacturing it wired as a current balun would be any different.

I think that it is the buyers who determine the market, and savvy sellers cater to the buyer's wants.

While anecdotal evidence abounds that 4:1 voltage baluns match up extreme loads better, and users mostly arent't interested in finding the root cause of the problem and fixing it, voltage baluns will be seen by most buyers and savvy sellers as the solution.

A good demonstration of the credibility of anecodotal evidence is the massive online support for the Array Solutions 4:1 Ruthroff voltage balun / ZeroFive unloaded vertical combination. The configuration drives high common mode on the coax feed line. (I should note that the sellers recommendation has recently changed to an unun.)

MFJ is no doubt one of the savvy sellers. They do BTW have some higher end ATUs with 1:1 current balun, as does the Ameritron label for those who want a current balun.

My own view is that achievement of highest choking impedance in a current balun is assisted by minimising stray capacitance to 'ground', so I would prefer to put a current balun in a non-conductive box, outside the ATU, on a foot of coax to the ATU. (This is one reason why I haven't tried converting my '949E to current balun connection, the windings are quite close to grounded metal and I expect stray capacitance to ground is higher than desirable.)

Owen

Hi Owen,

The internal modification would also demand a balanced tuner topology,
and not the garden variety pi configuration. Your stating stray
capacitance, coupling to ground, etc. is a preface to this.

Put simply, and as described, the 949E and its ilk are lumped
transmission line UnUn transformers. You might salvage the box in a
re-design, but it would require gutting the entire interior circuitry.

The 974 attempts to do this:
http://www.mfjenterprises.com/pdffiles/MFJ-974HB.pdf
and by their stated intentions, they are aware of the design issues.

I am sceptical of the "true balanced tuner" approach.

For one thing, I do not recall having ever seen measurement of the common mode impedance reported.

If the objective is current balance, high common mode impedance is essential.

Some folk seem to think that symmetric design is the sure path to success, but it isn't. If you take a 1:1 Guanella with extremely high choking impedance, the currents in its output wires will be almost perfectly balanced, irrespective of the voltage from each terminal to ground. If you placed 10pF of capacitance from each terminal to ground, you appear to have preserved symmetry, but the currents in those capacitors will not be equal unless the load is symmetric. In cases where the currents in the balun wires are almost equal and the currents in the capacitances I mentioned are not equal, then those capacitances have probably compromised common mode impedance.

Most implementations of a "true balanced tuner" have large stray capacitance from each side to chassis.

But, savvy sellers will offer them to the people who are attracted by the concept of a "true balanced tuner".

The joke of balun offerings is those designs purported to work well on isolated loads. If the concept of the load is the overly simplistic two terminal network, and it is isolated from ground, clearly current into one terminal MUST equal current out of the other terminal, no balun is required.

I have Linux on an old machine (P3, 1 GHz, 256M RAM) that really doesn't do
it justice. I was impressed that it recognized almost every USB device I
plugged in, new or old. I really should get a newer machine and load it up
with Ubuntu.

Sal

> connections/signals are for the radio.

Multiple Homer Simpson "Do-oh!" moments.

LDG was kind enough to supply me with the application note for
the interface cable.

I have two Icom radios. An IC-761 with an internal tuner and an
IC-726 designed to use with an external tuner. The IC-726 has the
mating 4-pin Molex connector.

The two signals are essentially a "request to tune" and an "tune
complete". The IC-726 has a TUNE button on the front panel for
telling the external tuner to do it's thing. (By the way, I do
have the matching AT-150 auto-tuner for the IC-726.)

All three of the tuners, the IC-761 internal, IC-726 external and
LDG have an SO-239 connector for the output and would require an
external balun to connect to an open wire balanced feed line.

The reason I was using the MFJ Versa Tuner with the IC-761 was
fairly simple. It has an internal 4:1 balun and connections for
open wire balanced feed lines.

Since I had to purchase a balun to use the LDG tuner I realized
that "Oh, I can use the Icom tuners with the balun as well."
That was my first "Do-oh!" moment.

Subsequently on researching the interface signals to/from the
LDG I realized that the IC-761 doesn't have a TUNE button or the
signals externally because the tuner is already inside the radio.
That was my second "Do-oh!" moment.

Once the MFJ 4:1 current balun I ordered arrives, the only question
that remains is whether or not the specified matching range of the
Icom tuners is sufficient to deal with my antenna system.

The Icom tuners are specified at 16.7 to 150 ohms.
The LDG Z11 Pro II is specified as 2-1000 ohms.
Oddly enough, the MFJ Versa Tuner has no specified range.

That is not quite correct.

Though the protocol is not published by Icom, and the implementation varies a little from radio to radio, the four wires are usually labelled and none are "tune complete".

Impedance is not a simple scalar quantity as expressed above. The 'specification' is incomplete, you would need to ask the sellers what they meant.

If for example, they mean the R component only, do they imply that X must be zero, or that X can be any value?

If they mean the magnitude, do they imply that any angle of impedance is acceptable?

Also missing is any bounds on efficiency.

I have heard from time to time on air, OMs boast that their tuner is so good, they have matched it up with no antenna plugged in. Obviously, efficiency is zero in that case. A tuner with lower internal losses might not achieve the same feat.

Did you miss the word essentially?

Since it bothers you. From LDG "Start Line." Ground this from an
external switch or open collector to initiate a tuning sequence by
the external tuner.

And "Key Line" This is similar to a PTT line to the transmitter,
but in this case tells the transmitter (which is capable of doing
it) to, regardless of mode, transmit a low lever CW carrier.

When the key line changes state because of a request to tune, it
turns on the transmitter. When tuning is complete, the key line
toggles back to it's normal state.

> Though the protocol is not published by Icom, and the implementation varies

If you put an indicator such as an LED on the key line watching it
change state is a pretty good indication of "I'm tuning" and "Tune
complete" regardless of what it's called.

Do you just like to argue? These are published specifications from
the manufacturer. If you have an issues with the validity of their
claims, take it up with them.

I suspect both Icom and LDG took the time to play with resistive
loads to verify the tuning range. If that is the case, then yes,
it's a simple scalar quantity. I doubt they took the time to fiddle
around adding a reactive components to the test loads otherwise they
would haved published a Smith Chart with a "We can match anything
within these bounds" as the specification for tuning range.

The /KEY line can be used to initiate a tune carrier, it is used to
sustain the tune carrier until the tx aborts or the tuner ends the
process, and it is used by the tuner to signal whether the tune was or
was not successful.

As someone who is a linux bigot (within the linux world, not talking
about other OSs) I finally had to admit that Ubuntu was ok.

But the current release is not.

I would advise you stick to the 10.04LTS (long term support) release.
Ubuntu 11.xx threw out the GNOME desktop and replaced it with rubbish.
I know no one that likes the new desktop that has used the old.

We can only hope that by the time 10.04 is deprecated that GNOME will be
back.

I have 10.04. Having only half the recommended RAM (per stated system
requirements) means I'm flogging the hard drive.

2506. Crossposting Permitted to rec.radio.amateur.moderated

Newsgroup: rec.radio.amateur.antenna
Date: 2011-10-01 06:00:02 UTC
From: rram@panix.com
Message-ID: <radio/ham-radio/moderated/crossposting-1-1317448801@panix.com>
Source record: 3507
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.dx,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.radio.amateur.policy,rec.radio.amateur.space,rec.radio.info

```
Posted-By: auto-faq 3.3.2 beta (PGPMoose V2.0, Perl 5.005)
Archive-name: radio/ham-radio/moderated/crossposting
Revision: 1.1 2009/04/12 19:42:04
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.
```

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

The current version allows you to easily revert to the old desktop if
you want. I did. But IMO there is not that much overall OS improvement
to do the upgrade unless you just want to try it which is why I did.

In Windows I use Firefox with the QuickJava extension. It puts on/off buttons at the bottom of the browser window that make turning on and off browser functions (flash, java, javascript, ect) quick and easy. When exploring I only leave text and images active. If I find a site I want to chance that needs flash or script I just turn it on and refresh. It's not foolproof of course but a different approach. And if I'm just reading text sites (newspaper, forums ect) I leave everything off but text and images and most of the flashy moving annoying ads which I hate are disabled which also improves the page loading time a bunch.

11.04 did. 11.10 does not. I'm sticking with 10.04 LTS. The new desktop
is for morons. They are obviously trying to appeal to tablet-brains.

Ah, I didn't realize 11.10 was out. My 11.04 is busted in that it
won't update so perhaps I'll take your advice and go with 10.04. Yes I
really tried hard to like that new desktop but just couldn't hack it
(pun intended) in the end... ;)

Nice. But that has nothing to do with what I was talking about.
Windows is, well, Windows. And X windows is Unix.

Neither have anything to do with browsing per se.

The Unity desktop is usable, but not for me. I don't think it was
designed for tablets. Methinks it was an attempt to use the "extra"
screen space afforded by 16:9 displays. In effect, it leaves the menu
on the left side of the screen most of the time. I switched back to
the older Gnome 2 desktop on 10.04 and am living happily without
Unity.
<http://www.geekgumbo.com/2011/05/04/switching-the-unity-desktop-to-the-gnome-desktop/>

On Fedora 15, the new and improved Gnome 3 is in my never humble
opinion a step backwards. The designers apparently decided that
configuration options should now be either well hidden, or
intentionally misplaced in non-obvious places. Some of the logic is
amazing. For example, requiring a logout before a restart. Is there
a problem with killing user processes that justifies this?

Meanwhile, KDE 4.6 seems quite good (I haven't used it much) but
really gobbles RAM. I also tried Mac4Lin with 10.04 and had problems.
Oh well.

At least we're not spending $160 for the privilege of BSODs! I like Puppy
Linux, which I believe is GTK on top of Ubuntu. Not pretty but incredibly
responsive. Will run on anything from first gen Pentium.

I haven't seen many BSOD's on Windoze boxes in maybe 10 years. The
only time I see them is when I'm playing with drivers or when I'm
trying to untrash the filesystem. I look at it differently. $160 is
a bit over 2 hours of my billable labor rate. If Windoze saves me 2
hours of time, I break even.

I think the desktop manager in Puppy Linux is JWM
<http://en.wikipedia.org/wiki/JWM>
apparently on top of Ubuntu.
<http://www.desktoplinux.com/news/NS5855706811.html>

I like AntiX for small footprint machines.
<http://antix.mepis.org>
PII with 128MB is about the minimum usable config although it will
allegedly run on older CPU's with 64MB.

Features and functions get added faster than bugs get fixed. The end
result is a bloated and buggy machine, full of useless features, that
runs at the speed of a snail. This applies to Linux distro as well as
Windoze and OS/X. "Bigger, Better, Faster.... pick any two".

You can run J Window Manager or GTK at the click of the mouse and a
restart of X Windows. If someone wants me to do Windows things they have
to give me a Windows box to do them on. I have an Atom netbook with XP I
use to feed my iPod. None of my ham radio stuff requires Windows. None of
my audio production requires Windows.

I use "BSODs" generically for any unrecoverable error that the 3 Finger
Mickey (or "Kill") won't fix.

Well, since you haven't been using Windoze much, you probably haven't had much experience with its stability. In my day job, I fix computahs, mostly running various Windoze mutations. I get very few unrecoverable errors, hung processes, comatose peripherals, or general weirdness, if the machine is in fairly good shape. No points for static electricity fried RAM, overheating CPU's (AMD early Athelon), buggy apps that won't die (Acrobat Reader 10.x and Skype), overly aggressive backup programs (Memeo), or various sync programs that fumble over their own semaphores (iTunes, MS ActiveSync). If I try hard, I can hang a Windoze box running any of the aforementioned. If I run alternatives, or run them in a VM sandbox, no problem. If uptime is your standard for reliability, then I can offer several weather stations running Windoze 2000 that typically stay up for months. For my personal assortment of machines, I only reboot after an update, or after a sufficiently large number of config changes to make sure I still have a working system. When a customer drags in a system that is acting "erratic" and tends to hang, it's usually either malware or the all too common bulging capacitor problem. Cleaning up the malware and replacing the bulging caps usually stabilizes the system. Incidentally, I only reinstall windoze from scratch if the malware has made such a mess that it would take me longer to fix than to reinstall.

Unless that sentences you to lots more hours later. Then you cost
yourself. Beware the easy path. Or at least research it.

I have to say the front end investment on Linux has been proven to be a
better investment than Windows "ease of install" and nasty programming
environment. For instance dot net does seem to leak.

Been there, worked all sides of the argument including Apple and I'll
take Linux and Apple in that order.

Actually I misspoke there. I have hard evidence that some parts of dot net leak. We are fighting a nasty problem at work because of that.

Managed code is not all it's cracked up to be. Especially when from certain software houses.

Funny, but my experience has been a lot different. Every month after Patch Tuesday, the phone lines would light up, as people's computers would stop working, or specific programs would stop. Some times it was because Microsoft would turn off something that was supposed to be a security problem, which just happened to be a needed feature for a program. I had one computer that every time it reached a certain place in the upgrade cycle, it would hose the OS, requiring a reinstall. Had to take a perfectly good computer off line. Even aside from instability issues - and a computer that might work one day, and not the next for no good reason is unstable - there were issues like killing DVD codec for Windows media player. Yeah nothing like a serving of pissed off users wondering why they couldn't play that demo DVD at their important meeting.

The fact is, my Windows computers had one problem after the other, while my Mac's just tended to chug along, and their users said we could take them from them after prying their cold dead fingers off them. Same for

me. I supported Windows, I did as much of my work as possible on the Mac.

There was 1 (one) case where an update made a problem for the mac users.

Windows? Couldn't even count.

Now that I'm retired, I will only be doing computer support for my family, and as my Windows Desktop just died last week, I'm going to be replacing it with a yummy 27 inch IMac, and the laptops will all be running Linux.

Free at last! Thank God Almighty, I'm free at last!

All apologies to MLK>

Not my pain or my decision. My customers are the Windoze users. I
also have a few Linux users. Mostly they run Linux servers and a few
desktops. In almost all cases, the decision of the OS is made by the
applications vendors or whatever apps the hired help is familiar with
using. I have little say in the matter.

One of my bad jokes is that I would be out of business if Microsoft
had done a better job. There's quite a bit of truth to that.

>I have to say the front end investment on Linux has been proven to be a
>better investment than Windows "ease of install" and nasty programming
>environment. For instance dot net does seem to leak.

I'm not a programmer, and therefore not qualified to comment on the
relative merits of programming environments. However, I have had to
deal with the multiple mutations of dot.nyet. It sucks. It's quite
common to have to uninstall all 4 mutations of dot.nyet, with a 3rd
party app, and reinstall the whole mess from scratch. I also have a
suspicion that dot.net is responsible for some bizarre application
crashes. I've seen memory leaks, but they seem to be coming from the
apps, not the libraries.

>Been there, worked all sides of the argument including Apple and I'll
>take Linux and Apple in that order.

I prefer Windoze, Linux, and Apple, in that order. My choice has
nothing to do with the quality of the product. It's in order of which
OS will make me money, and continue to support my decadent and lavish
lifestyle. Windoze needs help, I provide help, and therefore I make
money. At the other end, Apple users assume that if anything goes
wrong, it must be their own fault, and not that of the OS or apps.
They'll only ask for help if they're really desperate. Since I'm not
Apple approved, blessed, and authorized, I can buy parts or get inside
info. I'm also competing with AppleCare. Linux is a mix of the two.
Setting up complex SNMP monitoring and performance tuning is what pays
the bills. Dealing with hardware incompatibilities, is another Linux
favorite.

It's 100 percent true. An Apple costs more than a Windows computer - although not all that much when comparable performance is taken into account, because the Apple mentality does not sell computers that are ready to be obsolete, such as the horribly underpowered Vista basic machines. But I digress. The people who own Windows computers that I work on manage to feel that they have gotten a better and cheaper deal, when in fact, by the time they have paid me for a few fixes, they have surpassed the cost of "That pricey Apple computer". They also tend to quote the price of some half a$$ed cheap PC and something like the 27 inch i7 iMac when comparing prices. Check ot the high end Sony all in one, then we can talk about prices in more of an apple to apple fashion 8^) (not that you've complained about Apple prices AFAIK.

In in the professional world, no one seems to add the labor cost of the armies of support personnel needed to keep the Windows machines running. Adds a tad to the price.

I beg to differ. In 2009, I went through some effort to compare Dell
and Apple computahs selling just before Christmas time:
<http://802.11junk.com/jeffl/crud/Mac-vs-PC.xls>
Only the 13" MacBook was fairly competative with the equivalent Dell.
In all other cases, Apple was twice as expensive as Dell. I went
through considerable effort to get all the hardware as identical as
possible, but there are some discrepancies. The big one is that the
cost of the firewire port is not included in the PC pricing, because
few PC's actually use firewire. I plan to bring the spreadsheet up to
date sometime in November, when Christmas prices and goodies appear.

>because the Apple mentality does not sell computers that are
>ready to be obsolete, such as the horribly underpowered Vista basic
>machines.

Interesting. My customers problems seem to revolve around hardware
and software that was insufficiently tested and is therefore infested
with bugs. The problem is not that either was obsolete. It was that
they were permaturely released. Since whomever makes it to market
first usually wins, it's understandable.

Well, you're entitled to your opinion. I don't consider paying for
repairs in advance in the form of AppleCare as a great improvement.
I'll be sure to include the 27" iMac in my comparison, but it might
not be against an overpriced Sony. Nobody else has a 27" so I'll
compare the smaller screens. Very roughly, the Apple 21.5" iMac
starts at $1200. The Dell Inspiron 2320 all-in-one with a 23" screen
starts at $950.

>In in the professional world, no one seems to add the labor cost of the
>armies of support personnel needed to keep the Windows machines running.
>Adds a tad to the price.

I don't have much contact with IT except when they get into trouble.
As far as I can determine, most of IT consists of supporting users,
not machines. As near as I can determine, the level of user support
is about equal, whether Windoze, Mac, or Linux.

I'm not that sure about that. At work we still have Windows XP machines
bought in 2001, and while they are very slow they still work and can
be used e.g. as Citrix terminals or for Microsoft Office 2003.

They still receive security updates from Microsoft.

Apple machines from that era are long obsolete and receive no support
at all.

2533. On topic.....vertical antenna on metal patio cover

Newsgroup: rec.radio.amateur.antenna
Date: 2011-10-10 17:59:57 UTC
From: Wayne <mygarbagecan@verizon.net>
Message-ID: <j6vbqv$sv2$1@dont-email.me>
Source record: 3534

A few weeks back, I solicited info on a vertical antenna mounted on a metal patio cover. Here's the story to date.

First, I put up an Outbacker by using a standard automotive rack mount clamped on the conduit above the metal patio cover. The Outbacker was installed simply because it was easy to do, and I have one. Results were similar to what would be expected from an Outbacker mounted on a car. There was an unacceptable amount of cordless phone interference on 20 meters. Performance was acceptable on 10-15 meters.

Next, I removed the Outbacker and installed a 8.5 foot whip antenna. The antenna is resonant at 27.8 Mhz with about a 1.1 VSWR. At 28.5 Mhz the VSWR measures 1.8, and at 24.9 Mhz measures 2.3. Measurements were taken through about 30 feet of RG-58.

Performance of the whip is quite good on 10 and 12 meters. 12 meter performance seems better than 10 meters, but it isn't clear that propagation conditions influenced the outcome.

More experiments will be performed, but so far, so good. The unloaded whip is a simple way for me to operate on 12 and 10.

I looked at the all in one's. Dell doesn't even sell an i7, or even an i5 Biggest they have is an i3, Don't have a 27 inch monnitor, don't have a 1 TB hard drive. In addition the all in one Mac's have non-laptop components.

That's the issue I was referring to, Jeff. the Mac is called "too expensive", and it is compared to a machine that doesn't exist, so a cheaper machine is trotted out as a comparison.

So yes, the Mac is a whole lot more expensive than a machine that is a whole lot less capable. And infinitely more expensive than a machine that doesn't exist.

As I said, the closest thing I found is a Sony, and it's over 2K for a much smaller screen. Do not want.

> The big one is that the

I do use firewire. And will use Thunderbolt. Check out the specs vs USB3.

Mine tend to revolve around security issues, and updates that turn off needed functions to "enhance" security. As I joke with them, I note that the most secure computer is one that doesn't work any more.

>> But I digress. The people who own Windows computers that I

Don't use Applecare, and don't need it. The one issue with the bad
Rubycon caps a few years back was taken care of via recall. And that hit
many manufacturers, Dell included. I did have a server power supply go
bad once. Haven't counted the PC machines.

> I'll be sure to include the 27" iMac in my comparison, but it might

And there we go. I use a 27 inch Imac at work, and I don't want
another dinky screen.

As far as my outside computer support goes, I can make up that
difference in a short time. A couple service calls, and they might as
well spent the extra money on the Mac.

Or they can try the Geek Squad.

>> In in the professional world, no one seems to add the labor cost of the

Windows and Mac. Windows is around 95 percent of the work. The biggest
problem on the Mac side is the permissions, a side effect of switching
to a Unix based system. If not for the Windows support, I wouldn't do
support at all (permission fixes take mere seconds. Weird situation,
since I'm actually a videographer.

but yeah, I'm entitled to my opinion, and you are entitled to yours. If
you want to compare lesser Windows machines to Mac's have at it.

I do have the experience of working a lot with both types - actually
Linux too, but only at home. A lot. 8 hours a day with the Mac, maybe 6
a day with Windows. I don't dislike one or another, but I do put a
premium on the thing working. My Mac's work a whole lot more, and allow

me to meet my deadlines much better than the Windows machines. And that part is fact, not opinion.

Don't think I was arguing about that. If you can run XP on the computer, M$ will send updates. Be careful though. I had a HP Pavilion, bought in 2005, and at one particular point in the update process, it gets hosed. I ended up having to take it offline after the third time it happened.

My G5 machines still get updates.

Look, if you want, use the Windows machines. I don't really care. I do have in depth personal experience with both, and if my job was to support the Mac's I'd be out of a job. With the Windows machines, there is a lot of job security. Believe or do not believe.

My favorite part of working with the Windows fans is when I talk about someone getting a virus, or an update hosing their machine, the first thing they say is "Oh, I've never gotten a virus, then they go on to describe "there was this one time" and tell about how they got some virus that they had to wipe the drive to cure (or somesuch)

If you are happy with Windows, and it never gives you any problems, then by all means use and enjoy.

2536. antenna question

Newsgroup: rec.radio.amateur.antenna
Date: 2011-10-11 02:58:03 UTC
From: Michael Coslo <mjc5@psu.edu>
Message-ID: <j70bc2$g87m$1@tr22n12.aset.psu.edu>
Source record: 3537

Taking a break from computers, I had an actual practical question about an antenna. Sort of hypothetical, but maybe some practical use.

Situation:

Yard with a maximum antenna possibility of 100 feet. Height around 60 -70 feet.

All band is desired

in line with that, a decision to run ladder line (not window line)

Obviously, a tuner will tune the antenna.

But an antenna cut for somewhere in the 75 or 80 meter band is often touted as a good length, around 130 feet for this antenna.

Is there an advantage to loading the antenna to place it in the band, and tune the rest, or just to string up in the available space?

Perhaps something to allow it to une easily on 160?

Or, is there anything that would contraindicate using this approach?

Vertical antennas work great if you get them a few feet in the air. I
need a second antenna for the higher HF bands, I may try a 102" whip
myself.

I'd try an inverted V cut for 80

Mike,
Would it work? I think it will certainly work. That doesn't say how -
well- it would work, naturally, but you could put some kind of signal
on almost any band.
One option with that 100 feet and an 80 meter 'length' is to just drop
about 15 feet straight down (or tilted?) on each end of that 100 foot
span. That might even work for an 160 meter 'length' but not real
well, sort of, who knows?
One option on making something link that 'tunable' is by varying the
feed line length. Or, have a really 'capable' tuner. I doubt if it
would be the "best" radiator in the world, but it can certainly be
made to work.
- 'Doc

(Wish I had that 60 - 70 foot height capability!)

As offered, dropping ends.

>Perhaps something to allow it to une easily on 160?

The 80M length with tuner shouldn't be a problem.

Didn't mention it, but the top of the patio cover is at about 9 feet. It is
about 16 feet by 25 feet.
The whip is a cb whip that I was going to cut to length on 10m. After
trying it on 10 and 12 through a tuner I decided to keep it as is.

Indeed it is stated as the minimum length andtenna (being a half wave on the lowest operating frequency), fed with open wire feed of any type, and touted as a no-brainer, you can't go wrong.

As with most simplistic advice, it is flawed.

You gave lots of info on the system, well done, but ommitted the preferred feed line length.

It may well be that your preferred feedline length should dictate the dipole length.

In theory, for 80m use, I don't see much benefit to cutting it exactly
for 80m. The difference in matching loss should be fairly unnoticeable
as long as you are in the general ball park.
Ladder line should be pretty low loss, even with a high SWR.
So if there were to be excess loss, it would likely be the tuner.
And in this case, I don't think the difference would really be
noticeable on the air.
But... If it were me, I'd probably cut it to length anyway. But only
for the reason that I might decide to use coax at some later
date, and could still use the same wire. Or.. at least make it
too long, not too short.. That way it could be re-used with any
kind of line. But, maybe I'm just overly cheap and hate to see
a perfectly good stretch of wire go to waste.. :/

For 160 use, I'd feed it as a single conductor. Either short the
feed line, or feed just one leg. I'd generally prefer to short the
feed line to add more top loading. Makes it act like a T vertical.

If you fed one leg, it would be like an inv L. Either way should be easier to match with a lower loss than trying to feed it as a 1/2 size dipole. The tuner loss will get you in most cases trying to do that.

Lessee, I have standoffs holding the present window line, and can back
of the envelope this. five feet to the roofline, then 25 feet to
transition to where it heads verticaly. Then allowing for some droop,
I'd say another 40 feet given the 20 foot roof height.

So we're looking at around 90 feet total, not counting the foot or so in
the house.

One of the risks of using a centre fed dipole with arbitrary open wire feed is that you may find the impedance at the tx end of the line to be extreme on some bands, driving problems with volage baluns, and ATUs.

In the case of a 80m half wave, feedline lengths near 60' and 180' are likely to be troublesome. Same dipole on 40m and feedline lengths near 60' and 120' are likely to be troublesome.

Some folk would advise feeding at a current maximum, but of course, for this dipole, a current maximum for 80m at the tx end of the feedline is a voltage maximum for 40m.

Your 90' option might well be effective in avoiding some of the impedance extremes on the lower bands that damage componets, cause excessive loss, or are just difficult to match.

Make it 102' and you could hang a G5RV for 75m, 40m, 20m & 12m.

> Or, is there anything that would contraindicate using this approach?

The SWR on the ladder-line will be very high (~30:1) on 75m and too high on 160m. When a dipole is less than 1/2WL on the lowest frequency of operation, the feedpoint resistance goes down and the feedpoint reactance goes up as the frequency is decreased. As the antenna-length/wavelength ratio goes down, the SWR goes up. Here is some information on a 130' all-HF band ladder-line fed dipole.

http://www.w5dxp.com/notuner.htm

One could short the ladder-line wires together and feed the antenna against ground for 160m operation.

The support costs I've noticed, starting with IBM 360/65 (1973), are
people followed by people followed by people. Somewhere below the
people is hardware.

Been in the middle of it since 1975 starting as a programming assistant
in a college data center. Where we presented decks to the priests.

As a programming assistant the most frequent things I saw were questions
from the grad students like - "How do I make it fit?", "How do I make it
fast?", "Why doesn't it work?". Users who would spend 18 hours a day
dug into the math of what they were trying to solve, but refused to
spend 4 hours once learning the tool they used to solve the simulations.

I knew nothing of what they were trying to prove. But I always managed
to get the programs to fit, run fast as possible, and not "doesn't work".

Some things never change.

Mysql is malware itself, purporting to be a relational database, written by people who couldn't be bothered reading a book (for example) to learn what a transaction is. More harm and data loss can be blamed on people trusting it than on any malware.

Bill, don't know if you got an answer or not, but just saw your note, and though I would have sworn it would combine gz filed I just tried it and it errored on combining two adjacent dem.gz files but after uncompressing combined them fine.

I use gunzip for uncompressing.

Also, mine identifies as version 10.0 build in 2006. Version 7 may be too old, I think they kept developing after the author retired. I may be confusing this with another free package, but I'm pretty sure that's it. In fact I need to upgrade.

The cordless phone interference may be due to the power supply/charger. (I have a little wall wart that I use for my 220 HT during weekly local nets. It's so nasty that I need to unplug it when we shift to HF. Someday I will replace it. Someday I will do lots of things.)

Yes, quite likely as the wall wart is located about 1/4 wave on 20 m from
the antenna, and there are various possible paths. With the weather
moderating, I'll be doing antenna projects soon. The goal is 40-10 meters.
I have a separate 6 m whip on the patio cover also, but it doesn't seem to
operate as well as an attic dipole. I'll verify that when 6 opens up a bit.

You all know that the frequency from a satellite is changing.

Does anybody know if the frequency from a spacecraft reacts on the orbital speed of the Earth.

No, what you hear is mainly due to the orbital speed of the
satellite around the earth. The satellite has a speed relative
to the observer, and the resulting doppler shift makes the apparent
frequency of the satellite change.

When using a linear transponder, the situation becomes more complex
because both the speed relative to the transmitter and the speed relative
to the receiver have to be taken into account.

I have found the two old measurements:
"In 1818 Arago found that the refraction of a prism for star light was the
same for light incident in the direction of the earth's orbital velocity v
as for that coming in the opposite direction. This unexpected null result
was explained that same year by Fresnel's ether-dray theory, which assumed
partial ether entrainment in transparent media by an amount depending upon
the first power of v." From: http://www.3rd1000.com/chronoatoms.htm

And:

2. Vogel, H. C., "On the spectrographic method of determining the velocity
of
stars in the line of sight", Monthly Notices of the Royal Astronomical
Society, Vol. 52, p.87, 1891 >
"The first result of any importance which the spectrographic method
furnished was the proof of the influence of the Earth's motion on the
displacement, which the earlier direct observations had failed to show
with certainity. [...]" From:
http://adsabs.harvard.edu/abs/1891MNRAS..52...87V

Who was right: Arago or Vogel?
The spectroscopy and the spectrography are not accurate.
The radio waves are.

The Doppler effect comes into play anytime two objects are moving relative
to each other.

Ham satellites often go up on one sideband and retransmit on the opposit
sideband to help counter this effect.

Now we know that the frequency from the stars reacts on the rotational speed
of the Earth (in agreemment with the Michelson-Gale experiment).

By the analogy the frequency should not react on the orbital speed (MM
experiment).

But I could not find the answer.

2568. Trap antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2011-10-20 12:19:56 UTC
From: béo-master <beorien@wanadoo.fr>
Message-ID: <4ea011cc$0$30756$ba4acef3@reader.news.orange.fr>
Source record: 3469

HI,

I picked up two coils that could be a trap for the CWA-840 COMET
antenna. (They have two stickers "CL-840").
The manual of the CWA-840 says : 40/80m dipole.

I found amazing that there isn't any capacitor in // of these coils...
These coils measure 76uH.
Could someone tell me how they works ?
In the manual of the CWA-840, each leg of the 7MHz section, is
11.1meters in lenght , wich, it seems to me, that it is rather longer
that 1/4 wave. (10.1m).
Why ?

Thanks a lot for your answers

CWA-840:

-----[ ]-------------ooo--//--
2.3m coil 11.1m balun

> What is the "frequency" from the stars ?

Each waves has the frequency. The light frequency measured on the Earth
has the diurinal changes (in agreement with the Michelson-Gale experiment).
But what with the annual changes?

All coils are self-resonant at some frequency. Wind it right and off you
go!

Good point, Sal. I hope the OP has a GDO to tell him the self-resonant frequency. If not, there are other ways.

John, KD5YI

> These coils measure 76uH.

That is a rather simplistic characterisation of the trap. If you were to measure its impedance over a wide range of frequency, the data would give a better idea of the extent of any parallel capacitance (and there has to be some, even if only stray capacitance. Somethimes the capacitance is between some metal tubes that make the end supports for the trap.

Note that measuring the impedance of traps is very challenging.

> Could someone tell me how they works ?

The trap introduces some reactance and resistance that is intended with appropriate conductor lengths, to give a modestly low VSWR at the frequencies of interest.

The traditional explanation is that they are resonant at one of the frequencies of operation, and act like a switch, cutting off current to the outboard legs. Of course, current would flow in the outboard legs eve if you used a physical switch.

That explanation is appealing, but limits your options. There are advantages is making the resonant frequency of a trap fall outside the bands of interest.

The trap is probably self resonant below 40m... but that is just a guess
from experience of having designed such things.

This is not a trap antenna:

1)- At 40 meters the coil works like a medium impedance insulator,76uH
represents 5300 ohms.

2)- At 80 meters, the antenna works like a vertical mobile antenna, the
coil resonates with the 2.3m section.

I made several of these antennas years ago, and the 40 meter section is
always longer than in a simple 40 meter dipole.

Hi
I have a sauna with electric heater 7000watts. Nice area on top to put some rocks and I see others have suggested lava rocks. What if I put granite or limestone? That is what I have there now, they haven't cracked or exploded after spraying water on them. They look nice, some red, some different colors. Is there any harm in using granite or limestone apposed to using lava rocks? I am sure they were all the same a few million years ago,,, any reasons why I shouldn't use the granite or limestone rocks? Radiation? Emmisions of sometype? inevidable that they will explode? nuclear meltdown of some kind? I figure the temperature is around 200 or 300 degs.

Any thoughts please and thanks?

Hey, sorry it is off topic,

But received intelligent advice here before, thought I could hear some thoughts.

To answer a bit of my own question, I found that certain granite rocks handle well up to 800 degs. I thought regular iron turned red about 700 degs. The rocks I have are simply right from the river side and not been treated or anything. Just curious as to other concerns or issues that may come to mind. Maybe I will tell you in about a year what the experience is. Maybe too simple a question.

Ok, Ok,, I will go

Wow, not a very friendly group.

But I did manage to learn a lot about the rocks this evening, I got a lot of opinions from googling, mostly of dealers with their opinion. Some had bags of granite rocks for 80 dollars, plus shipping, plus taxes.

I will still watch the group for any interesting comments from those in the know, any interesting point or opinion is appreciated.

Any fungsua people?

We tolerate (sort of) off-topic wandering/rambling/babbling by regular
posters.

Try going to a geology group and asking them about ham radio. Or go to a
Led Zeppelin Group and ask about Sixth-Century Bhuddist funerals.

See how that works? There needs to be some linkage.

No problem gents,,

I did look into the geology groups and none were active, active on my news server. And I have learned a lot from this group, lots of knowledge within this group, I have made all my antennas. I completely made my sauna, right from scratch. I was simply curious about the rocks, if there were any theories as to their selection or why some were selected over others. I supposed it is a matter of preferrence. Did you know that rocks age several thousand years each time you heat and cool them? In accourdance with errosion? And I also learned a lesson in feng shui as these rocks cause a situation better than viagra, as when my asian gf came into the sauna with me there last night, well, lets just say we learned a few things there. None of the rocks exploded, I intentionally coolded a couple of them instantly in a bucket of ice water then back on the stove then cooled and nothing cracked or exploded like I read somewhere. Some of them were turning colors but I might attest that to the fluid replenishments, But still a bit curious why some sauna places scream about lava rocks, and forbid granite rocks, while others sell granite rocks. I suppose about 4 million years ago they could have been the same. So any geological advice from anyone in the know is awsome. 73s

Hmm, let's see, crystals are often referred to as "rocks" so maybe it's a
stretch, but ...

And granite contains quartz, a constituent of crystals.

And he/she has been polite in spite of some of the responses.

Tuuk, we aren't all ARs.

Yes, there are many legends in their own minds on this group.

What intrigues me is why, when a post is considered 'off topic,' even labeled 'Off Topic...' the reader doesn't just move on to the next post but has to respond with some nasty, snarky, demeaning bullshit. I guess some people are just wired so they have to feel superior even though their behavior causes them to appear insecure and incompetent.

Hot rocks will crack when you pour water on them. That's why you need
igneous stuff like lava (at Barbecues Galore). Get a squirtgun.

or C from the winding of the coil to the surrounding tubing.

Or the "self C" of the coil (viz Medhurst's formulae for self C of an
inductor)

There's a goodly bit of empiricism in trap design. You can use basic
physics to calculate, but there's enough non-idealness in most
construction techniques that the calculations get you to a starting
point. (e.g. you could model the transition from the antenna element to
the coil in the trap with a lot of detail, or you could just build one
and try it, then adjust)

Here's a (not very realistic) example of how it might work

Say you want an antenna that covers both 10m and 15m. You start with a 10 meter resonant antenna. Now hook a trap which has very high impedance at 10m on the end of it. Since it's high Z, not much current flows, so it doesn't change the 10m behavior very much. But, you also want it to work at 15m. So you figure out how long an additional element you need to put "outboard" of the trap to get the system to resonate. Typically, the trap is a parallel LC, so below resonance, it looks somewhat inductive. Since a short element looks capacitive, the added length for 15m will be shorter than it would be without the trap.

There's a whole raft of design approaches about where you put the resonance relative to the frequencies of use, and how you want the current distribution to work, and then there's all the "what's practical to make and manufacture" and "tolerance to misadjustment/weather/aging".

You can get a pretty good start with a modeling code like NEC, but eventually, you've got to go out and start fiddling in real life, because almost all traps are not precisely modeled by NEC for a variety of reasons.

Well, some sauna specialists prefer non-porous rocks to others, I am not
sure if the translation "soapstone" is known or correct, but it's dense,
not porous as limestone and has good thermal storing property.
Granite probably don't break easily as it's hard and solid, but
thermal storing properties are not the best.
The one popular stone used is the olivine, there could be several
variants of it.
Don't know the availability of "soapstone" in your area or the price of
it in your quantities but it could be one choice to try, at least on top
layer of stove.

Not inevitable, but entirely possible, and with potentially bad
consequences (e.g. "flying hot rock fragment puts out somebody's eye").

Granite *may* be safe enough, as it's a metamorphic rock which has
been heated to high temperatures at least twice in its lifetime.
Depends on whether that particular granite has cracks in it (some
does), how much moisture or water it has been exposed to, etc.

I would avoid limestone, as this is a sedementary rock which is
deposited from water and has quite a bit of water bound up in its
structure.

It's really a question of "How lucky do you feel?"

granite is igneous. gneiss is metamorphic from granite.

The hazard is, as you point out, voids full of water that superheat, and
then flash to steam. Sort of like the spalling from lightning current
flowing through corroded bolts in concrete.

So it depends more on the structure of the rock than precisely whether
it's igneous, sedimentary, or metamorphic.

Thanks all, great tips.

Still trying to figure out somethings on this sauna, it is one of those home made from scratch things.

I appreciate all advice. Excellent group, lots of knowledge here, I have benefitted from your advice in the past,,, and I will in the future.

Thanks again and 73s

Best regards

I have had an interest in the so called coax traps, and just in the last week or so, make some headway with some good measurments of the underlying inductor formed by the coil of coax shield. There were some surprises. For those interested, see http://www.vk1od.net/antenna/coaxtrap/index.htm .

Short of performing Medhurst style measurements on a range of inductors, there is no way to be sure that the effects observe apply generally, or what a more general model might be.

Say, after following the link, above, I just took a look at that AIM4170 web site and it looks like it's more trouble to get it up and running than most things. A lot of the steps are left to the imagination ... or they assume a whole lot about what potential buyers already know.

Anybody want to toss me a bone in the form of reassurance that it's easier than it looks? Cables, adapters,serial-to-USB (a known PITA), etc.

Thanks in advance,
"Sal"

Sal

I assume you are talking about the AIM Forum, here:

http://aim4150.proboards.com/index.cgi?board=analyzer

Yes, there are many questions about AIM4170 operation there, but look
closely at the dates of the messages. Most of them are now very old. The
software has settled down very nicely now, and the instrument is indeed
very easy to set up and use.

To find out all the information you need, download the latest version of
the software (currently in AIM_846.zip), from here:

http://www.w5big.com/prog_update.htm

The download contains the AIM software (which you can run in demo mode
without the AIM hardware), plus the manual.

There is a fair amount of literature on L and C (and loss) for shielded inductors, which is what a lot of traps look like.. the ones which use the C to the surrounding tube, anyway, like in the 4,5,6-BTV. Some papers have generic cookbook-ey design equations which might be useful (although I don't have any citations off the top of my head).

For a bare coil of the appropriate L/D ratio, Medhurst will get you in the right starting place.

The problem would be things like manufacturing variability, if you're copying (or writing instructions) one-off design. Stuff like 'how thick is the enamel/polyurethane/PVC insulation'.

Sort of like the measurements of Z and loss for zipcord. The dielectric properties aren't controlled in manufacturing, so what you measure on brand X, 16 Feb 2001 may have little or no relation to what you measure on brand X, 20 Oct 2010 vintage.

Sal, I bought an AimUHF, and it worked fine out of the box.

I suspect that the problem that most hams encounter with analysers and VNAs is that the knowledge of basic complex numbers, AC circuit theory, transmission lines, and antenna systems does not 'come in the box'.

If acquiring such a thing is the stimulus for expanding knowledge on those topics using the box as a learning aid, that is great. But to many, they are safer to just treat it as a VSWR measuring device.

I am staggered by the popular advice offered to newbies who ask 'why is my VSWR high' on eHam and QRZ to borrow an analyser. The advice appears to offered mainly by people who don't understand the instruments, and possibly have never used them effectively.

A classic example is the advice to connect the instrument at the shack end and tune for resonance, for as everyone knows, "an antenna just ain't gonna work any good unless it is resonate (sic)".

The getting of knowledge just isn't a priority in a world of instant gratification.

Owen

All noted.

Many readers will recall my interest over more than a decade in predicting the effective RF resistance of the outside surface of a braided coax shield, especially when it forms a solenoid... as in the coax traps.

The last round of measurements by VK2KRB were most interesting, because they strongly suggested that Q was not proportional to root of f as Medhurst and predecessors observed for round copper wire (and of course, R was higher than for an equivalent sized round copper conductor).

Jim, interesting that you mention ZIP cord. I have seen a number of articles recently discussing the TL characteristics of ZIP cord, and again many readers will recall Jack Smith's measurements published here about 10 years ago.

I recently put a new TL calculator up, it uses input parameters of Ro, vf, k1, k2 to solve problems similarly to the older TLLC. It is at http://www.vk1od.net/calc/tl/atllc.htm . I wrote an article with some examples of using it at http://www.vk1od.net/calc/tl/atllcEx.htm . Example 2 plots Jack's data on ZIP attenuation from back then. A stunning set of measurements, and statistically tighter than I have seen from any one else. Nevertheless, I see a wavelike shape to the error between actual and the model, a growing sinusoid that prompts the question of why, was it some common mode effect and radiation.

Owen

Dear Group: An echo: the AIM4170 is the greatest thing since sliced bread (or NEC) for serious antenna people. I use one with an inexpensive- very small, slow, lap-top to great effect.

The device is also ideal for measuring real components. The ability, if you buy a small set of high quality resistors, to calibrate out the effects of fixtures is a delight to use. I have a GR bridge. It has long been the standard. But my goodness is its use a lot of work.

Note that the device can tell the sign of the phase and I have found that it works well in the presence of strong signals. Indeed, one feature is that the device may be asked to scan a band of frequencies and display the stronger signals found. It is also very easy to calibrate the internal frequency reference to WWV. All of this with only one moving part - the on/off switch.

Thanks, Ian,

I did look at the forum briefly, but my reference was to this page
http://www.arraysolutions.com/Products/AIM4170.htm and one
or two links out. There were fleeting references to several operating
systems versions, as well as talk about USB-to-COM-port adaptation,
which scares me. (Never tried it; numerous horror stories are extant.)

I gleaned no real knowledge as to what I needed to buy to make it
work with both my WinXP box in the shack or my WinVista laptop.

I'll grab the software, load it and take it for a drive. It's not that I'm
some
Chicken-S kid who needs a lot of hand holding. (I have seven computers,
running everything from DOS 5.0 to Vista, with Mac OS 10.5 and Ubuntu
Linux thrown in.) I just don't want to spend $700+ for a leap into the
abyss.

Thanks for the advice.

Thanks, Owen,

I understand the world of complex numbers and vector impedance
well enough. My concern is whether I can make the thing work with
what appeared to me to be a dearth of hookup instructions.

How did you know what cable(s) to order? Are you operating with
a software COM port or do/does your computer(s) come with a
hardware COM port?

Anecdote:
Right after Field Day, for which I am the club Chairman, I followed a fellow club member's suggestion to try to get a network logging program running in preparation for next year. No dice. Hours wasted.

I followed many conflicting or wrong instructions; the best I managed was to get the two computers to each acknowledge the existence of the other -- but no more. No sharing of information and darn little help from the maker of the software, who assumes we are are all networking engineers.

Moral:
So, with the bitter taste of failure still fresh, I'm not really ashamed to act shy around this next (possible) installation.

As I told Ian, I'll try the software and see if it radiates warmth. It needn't be hot ... just not ice cold. :-|

The AIMuhf connects to the computer by USB, just a mini USB IIRC, and I
think they supplied a cable.
>

The software is a very important element.

In my experience, the software with these kinds of things is
amateurish... but usable.

I also have a TecTec VNA, but I avoid using it if I have something else
that will do the job, and the AIMuhf is usually better if a one port VNA
is up to the task.

You will see plots from both of those in the article
http://www.vk1od.net/antenna/7MDipole/7MDipole02.htm .

There are other ham grade VNAs, I haven't researched them deeply, some
may be kits or homebrew that leave you challenged to find some of the
parts.

Very interesting comments,,

I have had two or three visits to the sauna with high heat and nothing exploding yet or breaking down of rocks yet.

Thanks for all the great comments. Have great day and 73s

Interesting..
So the loss is about 0.12 dB/meter at 10 MHz, compared to, say, RG-58 at
0.04 dB/meter. That's a huge difference, especially since the center
conductor on the RG-58 is probably smaller than the zip cord (what was
the wire size? I think you cited 1.22 mm diameter? AWG 16? or AWG 18?)

The sizes came from Jack. 1.2mm is about #16.5.

The loss model suggests that dielectric loss is significant, even at 10MHz. Yes, I think you are correct that the inner conductor of RG58 is fractionally smaller. IIRC, about 80% of copper loss in coax is in the inner conductor, so the ZIP cord is at the disadvantage of having a smaller 'other conductor' compared to the shield of the coax. There may be some further degradation due to proximity effect. (Of course, ZO favours the ZIP line.)

It seems that the copper loss is close to four times what might be expected of round copper conductor. I don't know whether the conductors were tinned, and what the effect of stranding was.

Another possible source of loss is radiation as I mentioned in the earlier posting.

I note that Belden ceased supply of its 75 ohm twin lines, though I think they used PE dielectric. Their #13 (8210) seems to have higher conductor loss than accounted for by round copper conductors with normal skin effect.

I can't help but be suspicous that proximity effect is a significant part of the reconciliation gap.

Owen

2623. Crossposting Permitted to rec.radio.amateur.moderated

Archive-name: radio/ham-radio/moderated/crossposting
Revision: 1.1 2009/04/12 19:42:04
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.
```

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

Suppose my square loop antenna oxidizes. Does that affect its
characteristics?

Thanks,
John KD5YI

Yes. Its color changes :-)

Beyond that - as far as RF characteristics go - the answer is probably
"Yes, but probably not enough that you would be able to detect the
difference in practice."

What I believe would happen:

(1) As the surface oxidizes, its resistance rises. This will cause
some amount of additional signal loss, as current flows through the
resistive layer.

The actual amount of added loss will depend on the depth of the
oxidized layer, its actual resistance per square compared to
that of the underlying copper, and on the frequency (which
influences the *skin depth" of the material).

Interestingly, the greatest amount of added loss does *not*
occur when the oxide layer's resistance is at a maximum (near-
infinite), since little or no current will flow through the
oxide... it becomes "invisible", and the current will flow
through the metallic copper under the oxide. The losses are
highest when the oxide layer is (1) of moderate resistance, and
(2) fairly thick, compared to the skin depth. At this point,
most of the current will be flowing through the oxide, and
excluded from the metallic copper by the skin effect.

I don't know the actual numbers involved here (i.e. point of
greatest loss, for any given frequency). In practice I don't
think you'll come anywhere near these conditions for a copper-wire
antenna at UHF frequencies.

(2) Copper oxide is not electrically linear - it behaves somewhat
like a semiconductor (you can actually make a diode out of it).
This nonlinearity may result in the generation of some second-
and higher-order harmonics, and possibly some intermodulation
products, if a significant amount of current is flowing through
the oxide layer.

I doubt that this will be detectable.

(3) If you manage to get oxidation into your actual metal-to-metal
contacts (and not just on the surface of the metal) the problem

in (2) becomes a lot worse, since you can have *all* of your
signal power flowing through what amounts to a diode. Harmonics
and IM products can become much more of a problem.

In practice, I'd say that if you make sure that (3) is not a
problem... that is, all of your actual metal-to-metal contacts are
soldered or welded (or gooped with a conductive anti-oxidant paste
prior to assembly) you'll be OK, electrically. Surface oxidation
on the loop is unlikely to be a problem.

You could always scrub down the loop with Brasso, wash it
carefully and dry it, and then spray it with an industrial-
strength outdoor-rated UV-proof clearcoat. That would leave it
shiny and bright for quite a long time.

My prior 'Net search revealed opinions from at least two camps, so I thought I'd ask here.

Re: Color, I'll check with my decorator :-)

Re: Item (3), connections will be soldered.

I will be using #14 gauge wire as used in house wiring. I could leave the insulation on the wire, but moisture has a habit of wicking into the tiniest exposed crevice, as you are aware, and I'd rather not have to perform heroic efforts to prevent oxidation. By removing the insulation, I can at least observe the severity of oxidation and guess at whether it correlates to any observed communication problems.

Thanks for the complete and thoughtful answer, Dave. You have persuaded me to proceed without worry.

Loops are good! I have a full wave 160 meter loop, horizontal, at 35ft.
The copper begins to turn color within a month or so.

I see your address is Plano, TX. If you are down wind from any chemical
companies or oil refineries or houses that use oil heat, or even natural
gas users, the antenna and soldered connections will not just oxidize,
but will have other chemical reactions to the sulfur and other acids in

the air.

When I lived in Portland, Oregon, years ago, we and all the neighbors had oil heat. She sulfur from burning oil caused lots of corrosion on copper and soldered connections. Hope you have better results. As noted, clear plastic spray will help a lot on the soldered parts.

Plano is north of Dallas. The prevailing winds are from the south. That
says it all.

The antenna looks like a diamond and is only about 1 foot in its
greatest dimension. It will be mounted no more than 6 feet above ground.
If I give it some thought, I can probably design the whole project such
that the antenna can be replaced without too much trouble.

Thanks for your input, Paul.

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been
recently revived by an active moderation team. We are currently seeking
suitable information, FAQ, and bulletin articles from the entire
rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our
newsgroup.

We are seeking a replacement maintainer for the following information
bulletin formerly posted to rec.radio.amateur.* (and currently archived
at http://www.faqs.org/faqs/radio/personal-intro/ ):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article |
is that it does not mention newer amateur radio newsgroups created since |
it was written, including: |

rec.radio.amateur.antenna |
rec.radio.amateur.boatanchors |
rec.radio.amateur.dx |
rec.radio.amateur.equipment |
rec.radio.amateur.homebrew |
rec.radio.amateur.moderated |
rec.radio.amateur.space |

We are willing to provide any technical support necessary to get this
article updated and automatically posted again at a regular interval.
This would include establishing contact with the original maintainer for
any necessary permissions. We would prefer to seek a new, dedicated
maintainer at this time, rather than start auto-posting the original
article ourselves.

For more information about our newsgroup, see:

"The first observations of cosmic radio emission were made by the American engineer Karl G. Jansky in 1932, while studying thunderstorm radio disturbances at a frequency of 20.5 MHz (14.6 m). He discovered radio emission of unknown origin, which varied within a 24-hour period. Later he identified the source of this radiation to be in the direction of the centre of our Galaxy. From: http://encyclozine.com/science/astronomy/radio

I understand that the frequency "varied within a 24-hour period". It is the "diurnal effect".
And what about the 365 days period (annual effect)?
S*

It is not the frequency that changed, but the intensity. And not a 24
hour period, but 23 hours, 56 minutes, thus proving that the noise was
not generated or varied by the earth's rotation.

Yes. "His" transmitter "produced" many frequencies. But Karl G. Jansky was
the pioneer in Radio Astronomy.

Now are the spacecrafts. They use the two frequencies.
I have found the link:
http://chaos.swarthmore.edu/courses/Physics130_2008/Pioneer_Anomaly.pdf

""It is also possible to infer the position in the sky of a
spacecraft from the Doppler data. This is accomplished by

examining the diurnal variation imparted to the Doppler shift

by the Earth's rotation. As the ground station rotates underneath

a spacecraft, the Doppler shift is modulated by a sinusoid."

Probably in this paper is also the answer for my question: "And what about
the 365 days period (annual effect)?

Unfortunately I am not an expert in radio. Do you know the answer?

Why are you so obsessed by this question?

2638. Measuring transmission line characteristics

Newsgroup: rec.radio.amateur.antenna
Date: 2011-11-07 19:05:06 UTC
From: John S <sophi.2@invalid.org>
Message-ID: <j99a53$jn6$2@dont-email.me>
Source record: 3439

I have about 94 inches of RG-142B/U. I am using a Fluke 6061A signal generator, an HP 8405A Vector Voltmeter, and a Narda dual directional coupler. I have tried to measure the line characteristics at 434 MHz but I am not satisfied that the results are accurate. It is very difficult to get good short and open circuits at this frequency and I also wonder if the 8405A accuracy suffers since a short is well away from the nominal system impedance of 50 ohms.

What if I simply calibrate the 8405 with a short on the end of the line (the measurement plane) then attach my antenna and accept the readings? Will they be very far from the real value?

Thanks,
John KD5YI

The easiest way to get the characteristics of the line is to look up the manufacturers data. Somehow I don't think that this is really what you are looking for !

Irrespective of line length if its terminated in its characteristic impedance then you will only measure unity vswr. Open or short circuit terminations are easy enough to obtain. Having a known input quantity and measuring the return value will give you the line loss for that particular line length.

I suspect that its actually the antenna characteristics that you are seeking to measure ! In which case I would use a line, accurately cut, to be number of half waves long, then the impedance presented at the far end would be repeated at the near end. Of course you would need to have an accurately cut quarter wave length in order to determine whether the load was inductive or capacitive in nature.

I'm sure that if I'm mistaken some of the more knowledgeable will correct my errors.

He's not. He's just obsessed.

He loves to ask questio0ns, get answers, and then tell all of us that
any science newer than 100 or 150 years old is incorrect. Even when the
scientist in question changed his original theory due to newer and
better evidence.

It will happen. Just wait a bit.

Dear John S: Conventional wisdom and common sense suggests that measuring Zin (with an open and then a short at the far end) at a frequency where the transmission line looks like an odd multiple of 1/8 WL tends to provide the best quality of measurements to be used to characterize a piece of coax. Such measurements tend to result in two numbers that are similar. Extrapolation to 434 MHz should provide reasonable estimates.

The UHF version of the AIM4170 and its software will provide the values and do the indicated calculations. Of course, one needs to select the reasonable value (from the infinite inherently provided) for rad/m - but that is rarely an issue. Your equipment too should be able to provide the two values of Zin and a good HP calculator will do the rest.

Measurements near, say, frequencies where the coax looks like multiples of 1/4 WL produce numbers that are not favorable for calculation. Baron provides other ways to think of the task.

No doubt you know this, but others might not. 73, Mac N8TT

Once more:
""In 1818 Arago found that the refraction of a prism for star light was the
same for light incident in the direction of the earth's orbital velocity v
as for that coming in the opposite direction. This unexpected null result
was explained that same year by Fresnel's ether-dray theory, which assumed
partial ether entrainment in transparent media by an amount depending upon
the first power of v." From: http://www.3rd1000.com/chronoatoms.htm

Today's spectrograph astronomers assume that the effect is not null.

It seems to me that today's astronomers are wrong because in physics are
still null result.
So I am looking for the result from communication with the spacecraft.

I am a little confused about your objective. The subject line seems inconsistent with your discussion.

If you are trying to measure Z at the reference plane in the simplest manner, then what you propose in your last par should give you the magnitude and phase of the reflection relative to a s/c (where Gamma=-1).

This simple paired measurement of the reflected wave from a s/c and unknown load depends on the forward wave being constant. That is true if the Thevenin source impedance of the source at the coupler is equal to the nominal characteristic impedance of the coupler and the coupler terminations, cables etc that you use. That would usually be met by a standard signal generator etc, but some SSGs depart from ideal on their highest output settings (check the specs). Measuring the forward wave under significantly different loads will provide an indication as to whether you can assume that it remains constant with different loads.

I give an explanation of why Vf is constant when Zs=Zo at http://vk1od.net/transmissionline/VSWR/Zs50.htm .

You will recall that there is an ongoing argument that a ham transmitter is well represented as a Thevenin source with Zs=50+j0 ohms, as some accident of design. The article describes a simple test using an accurate directional wattmeter to demonstrate that under different drive level and different frequencies, that Vf is often not necessarily independent of load impedance and that calculations that depend on constant Vf (such a Mismatch Loss) are in error.

I should have explained that this simple approach assumes the coupler etc to be ideal, the measurement instrument accurate etc.

We make those assumptions in using something like a Bird 43 to find VSWR, you could use your test setup with comparable accuracy to find more than just the magnitude of Gamma (and hence VSWR), but also its phase and therefore complex Z.

I think I am the confused one. Do I even need to know the transmission line characteristics if I am going to short the load end and set the vector voltmeter for a phase reference of 180 degrees?

I am following the HP app note AN-77 and they do not mention a transmission line. They say to short the load end of the coupler. I need to get my antenna away from the test setup, so I add the transmission line.

Has this made any sense?

John

The problem is that these measurements are designed to be made
as close to the instrument as possible. Adding a piece of transmission
line adds loss and phase shift to the measurement.

So unless you know how to work backwards from the measure you get to
what you're really measuring at the far end, you won't really have a
valid answer.

John S <sophi.2@invalid.org> wrote in news:j9c2h9$c69$1@dont-email.me:

...

If you are not concerned with trying to calibrate out the directivity of the coupler (and if that is greater than the expected / tolerable Return Loss, you don't need to do so), and you have convinced yourself that Vf is independent of load impedance (as it will be if Zs=50+j0 and you use short low loss line, or a large attenuator at the coupler to control Zs), then the simple approach is to do the following.

> I think I am the confused one. Do I even need to know the transmission
> line characteristics if I am going to short the load end and set the
> vector voltmeter for a phase reference of 180 degrees?
>
> I am following the HP app note AN-77 and they do not mention a
> transmission line. They say to short the load end of the coupler. I
> need to get my antenna away from the test setup, so I add the
> transmission line.

And you understand that the Gamma found is at the reference plane (the plane of the calibrating s/c), and you can adjust it, or the calculated impedance to another point on a known feedline using the well known Telegrapher's Equation (http://www.vk1od.net/calc/tl/tllc.php solves this problem for a range of popular lines), albeit subject to error due to uncertainty about the known line.

(I did consider at one stage extending TLLC to allow specification of mismatch in terms of Gamma, rectangular and polar, but no one ever asked for it and I thought it not in demand. The complication is that finding Z from Gamma needs to use the nominal Zo of the test equipment, not the actual Zo of the lossy transmission line. I usually use a spreadsheet to perform the calcs, Excel can handle complex numbers using the COMPLEX and IM* functions either in the Analysis Tookpak in earlier versions, or built in to the later versions.)

An important thing to keep in mind is that while the measurements you make are of the TL in differential mode, it may be carrying significiant common mode components which will affect the differential currents. In making your measurements, if you change the common mode current path from the normal system configuration, you are measuring a different system and the results might not apply. There seems an unwarranted assumption in most discussion of such measurement projects that there is inisignificant common mode current.

> Has this made any sense?

Perhaps it is my turn to ask.

Agilen't AppCad can be a convenient tool for one-off calcs.

Nevertheless, there is value in see the results of measurement as you make
them, it helps to minimise the chance of leaving the task with errored
data.

> Zs), then the simple approach is to do the following.

I have convinced myself of nothing. Hence, my questions here.

I measured the coupler several years ago:

Narda Dual Directional Coupler...

435 MHz

Forward direction:
Coupling = -33.1 dB
Directivity = -56.8 dB

reverse direction:
Coupling = -33.5 dB
Directivity = -74.7 dB

The manual for the Fluke generator says it is 50 ohms output Z. I used
your Line Loss Calculator to find that my 2.4m coax is 50-j0.1 and
0.671dB loss.

Nice numbers, but I don't know what to do with them.

I understand very little.

The Fluke gen feeds the Narda dual directional coupler. The coupler
output has the 94 inches of RG-142B/U attached. The coax has all the
ferrite cores in my possession slipped onto it to moderate common mode
current. The vector voltmeter A input is attached to the forward coupler
sampling port and the voltmeter B input is attached to the reverse

coupler sampling port.

I put the best short circuit I can muster on the far end of the coax and set the vector voltmeter to read 180 degrees. I record the A and B voltage inputs.

I put the antenna on the far end of the coax. I read the A and B voltages and the angle between them. I use Excel to calculate the results as indicated in the HP AN-77 app note.

> Perhaps it is my turn to ask.
>
> Owen

I am aware of the common mode current problems and I do everything I can to minimize them. I don't know if I am successful, but I test the effectiveness of my efforts by running my hand up and down the coax and watching the voltmeter. I haven't been able to get all variation out, but some of the variation is due to my hand proximity to the antenna itself.

Back to you.

Hi, Jeff -

Yeah, that's what I'm trying to learn by my questions.

Obviously, the antenna can't be sitting in front of the test equipment
so I'm trying to find a way to minimize proximity effects.

I should have used a different subject for the post, I think.

Yeah, well, sometimes I get turned around in my quests and lose my way.

It is the antenna characteristics I am after. What I want to know is, do I need to know the transmission line characteristics which I use during the test in order to modify my test results to show the true antenna impedance?

What I want to do is build an antenna based on its radiation characteristics (as shown with EZNEC) and then measure its impedance (at the end of a few inches of parallel conductors) so that I can put in a matching network to give my source what it wants.

John

The problem is that whilst putting the unknown right at the instrument might solve some problems, it creates others, particularly when the unknown is an antenna system.

>>
>> So unless you know how to work backwards from the measure you get to

Well, you can work backwards as I explained, though again at the expense of some uncertainty (error).

...
> Obviously, the antenna can't be sitting in front of the test equipment
> so I'm trying to find a way to minimize proximity effects.

Don't overlook that the reference plane need not necessarily at the end of the directional coupler, it could be anywhere that you can conveniently or inconveniently apply the calibration s/c (eg at the antenna connector for flange as appropriate).

Try this on the bench with a substantial length of coax to the reference plane, and measure a 25 ohm load (pair of 50 ohm terms on a Tee). The reference plane is determined by where you apply the calibration s/c.

It was common practice using slotted lines to make such measurements with the slotted line a long way from the reference point, which might be quite close to the antenna, possibly a s/c applied at the antenna flange, or on a W/G switch near the antenna.

BTW, you have read the AN, and noted no doubt the issue with error due to the probes loading the test circuit. I would not obsess too much over perfection unless you are prepared to go to great lengths to try and allocate the errors and obtain a better result.

My mention of the common mode current path is very relevant.

You have test equipment that is 'not-balanced' and a load that is balanced or more likely 'not-prefectly-balanced' in a different way. That is likely (certain) to cause common mode current, which means the common mode current path directly participates in radiation, making the antenna different to your design.

AHA! I think this is the answer I was needing. So, if I short the end of the coax and calibrate my vector voltmeter I can then believe the voltmeter when it says my load is a certain impedance?

I don't know were I got the idea that I had to have the coax characteristics to be used to modify the readings for accuracy.

> Try this on the bench with a substantial length of coax to the reference

Okay. I'll do that as soon as I can find the instruments. They are somewhere around here.

I don't obsess. I'm usually happy with errors of less than 1.5 to 1
(depending on circumstances, of course).

Thanks, Owen.

Ok, be aware that sometimes that impedance is gauranteed to less than
full output.

If it is 50+j0, then your Vf reading should not change in magnitude with
load variation. If it does change, you have to factor it into the calcs
as in the AN.

> your Line Loss Calculator to find that my 2.4m coax is 50-j0.1 and
> 0.671dB loss.

Since it seems you are applying the cal short at the load end of that
line section, then its loss is not so important (so long as it is
stable).

Ok, that sounds fine. If find it helps to measure something that is
known. Do you have a pair of 50 ohm terms and a T that you can measure
and convince yourself that it is working.

Ok, but it remains a potential problem.

Yes, I am aware of that problem. Perhaps I will build a current pick-up loop and run it up and down the coax. I can use the sensitive input of the vector voltmeter or maybe my Boonton RF voltmeter. I can then try to minimize the common mode current.

Okay! This is another answer for which I was hoping. This simplifies
everything.

Thanks again, Owen.

Surely the antenna will have some means of adjustment ie gamma match,
and since you know that if the electrical length of cable equals a
number of half waves, adjusting the antenna to show minimum VSWR at
generator end, achieves your goal...

I just looked back at some of my data and I see that the Vf changes slightly with some loads. However, this variation is used in my Excel spreadsheet to calculate the results. All is according to the HP app note.

In today's physics is opinion that we can detect the angular motion (Sagnac effect) but it is impossible to detect the linear motion.
Who and when deprecated the famous null result?

Earth's rotation is about 465.1 m/s
Say the average frequency of visible light is 500THz

doppler shift is (Vr/C)*F = (465/ 3 * 10^8)*500 * 10^12 = 7.75 10^8Hz
So to see the shift you will need to be able to observe your light
frequency to an accuracy of about 0.00015%. Which would have been
impossible for Arago.

Of course the above figures are only true for light coming directly at
the observer ie on the horizon, so for other angles there is a Cos Theta
term to reduce the effect even more (to zero directly overhead).

2666. Re: Measuring transmission line characteristics

Newsgroup: rec.radio.amateur.antenna
Date: 2011-11-09 13:17:47 UTC
From: "J. C. Mc Laughlin" <jcm@power-net.net>
Message-ID: <3pqdnQ5ZEf7j4CfTnZ2dnUVZ_h6dnZ2d@bright.net>
Source record: 3367

Dear John S: My comment of a few days ago was written under the assumption that you wished to know the characteristics of the TL. It has developed that you wish to measure the impedance of an antenna at the end of a piece of coax.

The procedures for removing the effects of a fixture, which I expect to be in the AN and require a short, an open, and a known load, may also be applied to a piece of coax. The result is the ability to remove the presence of the coax and be left with the antenna's impedance.

I do this in an automated way with the "calibration" feature of the AM4170. One scans a span of frequencies three times storing information about what the coax looks like with a short, an open, and (usually) 50 ohms at the far end. This takes some time depending on the size of the frequency span and the step size. The stored numbers (stored in a very inexpensive, tiny computer) are then used automatically to calculate (over the same span) the actual Z at the end of the coax.

Doing this procedure by hand, which I have done using the numbers measured by a GR bridge, is labor intensive. Before the advent in 1972 of the HP35, it was real pain. One did not use very many frequencies! It appears that you are interested in only one frequency.

Comments about choking common mode are right on target. Owen Duffy is one of the good guys.

73, Mac N8TT

P.S. Do you have a call sign?

Yes, I know. Sorry for the misleading subject line. I should have
presented my query differently.

"In 1818 Arago found that the refraction of a prism for star light was the
same for light incident in the direction of the earth's orbital velocity v
as for that coming in the opposite direction".

The orbital speed is about 30 km/s. Todays radio methods are adequate for
0.5 and for 30.

The rotational speed was too small for everybody till 1925. In this year the
Michelson and Gale detected the Earth's rotation.. But nobody detect the
orbital speed.

The same is with the spacecrafts. The diurnal effect is confirmed. I am looking for the annual effect.

2669. Line isolator for VHF UHF

Newsgroup: rec.radio.amateur.antenna
Date: 2011-11-10 17:13:07 UTC
From: Tom Horne <hornetd@gmail.com>
Message-ID: <abad3160-672b-43cc-81b9-12f9e43ee308@p1g2000yqh.googlegroups.com>
Source record: 3370

Is a current balun or line isolator effective in limiting common mode
current from the outside of a coaxial feed line when the antenna is a
two meter & seventy centimeter dual band vertical? What sort of line
isolation would be best practice for keeping current off of the
outside of the coax shield?
--
Tom Horne, W3TDH

> Tom Horne, W3TDH

Yes, for current balun; not sure exactly what you mean by "line isolator";
it appears to be a choke, maybe just another name for choke balun. Let me
be on that.

You have some easy ways to make your own current balun, which might be
called a choke balun.

(1) Slide a couple dozen Mix 43 ferrite cores over the coax and secure them
to the coax close to the antenna. I say Mix 43 because it's pretty common.
Mix 31, 43, 44 and 46 are suitable for 2m choking. Mix 61 covers 440 but
not 2m. See:
http://www.fair-rite.com/newfair/pdf/CUP%20Paper.pdf for one company's view
of things.

(2) Wind a section of the coax (again, close to the antenna) into a fairly
tight coil of three to six turns on a cylindrical form. There are many
opinions regarding size and number of turns if you search the web.

(3) Some advice would have you wind a few turns on a ferrite toroid but it
would have be with a short section of odd, small diameter coax, since RG-8,
RG-58 can't be bent that tightly.

As to "best practice," that, sir, is far too risky to declare in a
newsgroup. (If I had a few thousand dollars more in test equipment, I might
risk an opinion.)

I will say that if you can manhandle the line -- grasping, waving,
wiggling -- and you see the VSWR changing, it's possible you've not gotten
it right, yet.

Tom,

I published a design for a common mode choke which had moderate choking impedance from 50Mhz to 150MHz, see http://vk1od.net/balun/G1-1-FT140-61/ . It uses four turns of coax on a 1.4" #61 toroid, and common mode impedance data is shown.

Most manufactured products and most ham designs do not include predicted or measured choking impedance data which is most often the key parameter in selecting a device. If you don't have that, you are guessing.

The design mentioned above might be adapted for 130 - 480MHz by taking a turn off, but I would be guessing. Without modelling and measuring, it is just a guess.

Whilst I have explored the W2DU style baluns on HF, I don't have any designs that are intended for your application. I am sure there would be viable designs for low power. A string of suitable clipons might be viable (if more expensive).

2672. Auto tuner matching range

Newsgroup: rec.radio.amateur.antenna
Date: 2011-11-11 22:58:57 UTC
From: Wayne <mygarbagecan@verizon.net>
Message-ID: <j9k9blemr1@dont-email.me>
Source record: 3373

I have an auto tuner whose specs for the output are:
"10 to 250 ohms"
Does that have any useful information other than perhaps the R part of R+j.

2673. Re: Auto tuner matching range

Newsgroup: rec.radio.amateur.antenna
Date: 2011-11-11 23:17:32 UTC
From: dplatt@radagast.org

>I have an auto tuner whose specs for the output are:
>"10 to 250 ohms"

>Does that have any useful information other than perhaps the R part of R+j.

That's not particularly comprehensive information, since it doesn't say whether it's R, or |Z| that it's describing, and doesn't say what frequency range this spec might apply to. It's likely that any auto-tuner (or any manual one!) will have different matching ranges on different bands.

This spec *might* mean "This tuner will successfully match most loads within a 5:1 SWR range, on most of its bands, most of the time."

Or, it might mean much less than that.

You could ask the manufacturer for a full specification on the actual impedances that can be matched on various bands (e.g. a set of Smith charts). They may or may not be able to provide them.

If you know what the switchable reactances inside the tuner are, and what the switching topology is (most likely a bidirectional "L" but it might not be) then you could calculate and plot the outer envelope of the matching range for any given frequency. The math isn't too terrible.

Not really as it could mean magnitude |R+j| or just R.

It shows that the author of the specs doesn't understand impedance which is two dimensional (real and imaginary part), and he is appealing to those hams (probably the majority) who think that the magnitude of Z (which is a scalar quantity like they have used) will win the sale.

If we read it litterally, they have given they have writen impedances with a real part and zero for the imaginary part. The equivalent VSWR (50) is 5:1 (funny that). It is not a very wide range tuner for those purely resistive loads.

That said, the information doesn't help much in selecting the tuner because you will almost always use it with a load where X is not only not zero, but quite likely much greater than the R component.

It is BS technospeak for a dumbed down pseudo tecnical buyer.

-
Thanks to all the responders. I assumed that the spec was to indicate a
general ability to match 5:1, but as Owen said, a dumbed down spec.

Anyway, it is an older Yaesu tuner with a lot of flexibility. I've used it
for years, but am currently considering some different antennas.

2679. Updated List 2012 Solutions Manuals, Instructor Manuals & Test Banks Collection. Largest Collection Over The Net !!!

You mean when earth is generally heading "towards" the galactic center vs when earth is heading "away" from the galactic center?

People doing deep space navigation deal with this all the time, since navigation is done by measuring the frequency of the received signal from the spacecraft. There's nothing special about it. spacecraft on some heliocentric trajectory, Earth on a different heliocentric trajectory. Measure frequency shift, they use to determine spacecraft trajectory by applying (mostly) Newtonian physics (you do have to use relativistic corrections to get the last gnat's eyelash of precision).

Since you only get to measure in one direction, you have to make assumptions about what's going on in the other directions, (e.g. cross range), which can lead to disasters (Mars Climate Orbiter, most recently).

You can do various forms of VLBI and DeltaDOR to get some cross range information, but nothing as good as what you're getting for range (where velocity and range are measured to mm/s and cm sorts of accuracy)

Yes. But on the Earth orbit are places when this speed is 0.5 km/s (only
rotation) or 30 km/s. (orbital speed).

Like the Earth and Mars.

>Measure frequency shift, they use to determine spacecraft trajectory by

They confirm the diurnal changings in the frequency. But what with the
annual?
>

Naw are the spacecraft at distances almost like stars. They are not on
heliocentric trajectory.

So I repeat my question:
" I have found the link:
http://chaos.swarthmore.edu/courses/Physics130_2008/Pioneer_Anomaly.pdf

""It is also possible to infer the position in the sky of a
spacecraft from the Doppler data. This is accomplished by

examining the diurnal variation imparted to the Doppler shift

by the Earth's rotation. As the ground station rotates underneath

a spacecraft, the Doppler shift is modulated by a sinusoid."

Here they confirm the diurnal variation in the frequency.

Probably in this paper is also the answer for my question: "And what about
the 365 days period (annual variation in the frequency)?
Unfortunately I am not an expert in radio. Do you know the answer?

S*

Yes, and, for instance, they measure the Doppler shift in the signals radiated from spacecraft/rovers in orbit/on the surface of Mars as they arrive at earth.

As expected, the Doppler has several components: one from the rotation of Earth, one from the rotation of Mars (for a surface asset), and one from the relative motion of Mars and Earth (which is periodic with about a 2 year, 2 month period)

No surprises, nothing unusual. In fact, *tiny* variations in the Doppler are used to compute the orbit around planets, and from that, infer the internal structure of the planet. Juno is going to Jupiter right now to do this, and the Doppler will be measured with a precision of about 1 part in 1E15 (measured over 100-1000 seconds).

All changes in frequency, of course. Load up the SPICE kernels, run the numerical integration, and the expected frequency pops out.

All spacecraft that humans have launched are on some form of either
planetary centric or heliocentric trajectory or a combination of both.
In any case, they are computable (viz. Gauss) and measureable.

>

>
> a spacecraft, the Doppler shift is modulated by a sinusoid."

That's somewhat of an over simplification, but it's essentially true.

The paper describes the technique used to measure the frequency.. A
signal is generated on the ground at 2.11 GHz, locked to a hydrogen
maser. that signal is radiated to the spacecraft, which uses a phase
locked loop to track it. The spacecraft sends back a signal with a
frequency/phase ratio of exactly 240/221 (i.e. about 2.29 GHz) which is
received on earth and compared with the same hydrogen maser.

>
> Here they confirm the diurnal variation in the frequency.
>
> Probably in this paper is also the answer for my question: "And what about
> the 365 days period (annual variation in the frequency)?
> Unfortunately I am not an expert in radio. Do you know the answer?

Do you want to know the magnitude of the shift? Earth's orbital velocity
is about 30km/s, so the fractional frequency change is 1 part in 1E4
(100ppm). That's huge compared to, for example, the change due to the
oscillator frequency aging. Considering that for deep space navigation,
frequencies are regularly measured these days to parts in 1E12, this is
something they deal with on a day to day basis at the Deep Space Network.

if you want more details, take a look at equations (3) through (6) on
page 11-12 of the 50 page paper you cited, which gives a nice detailed

explanation of all the factors they are taking into account. And, they nicely note how you can use the models to implement theories of gravity other than general relativity.

equation 4 describes the light time (which ties to doppler measurement) and includes the relativistic corrections as well.

they take into account things you haven't mentioned such as changes in the earth orientation (precession, for instance), changes in earth rotation rate.

"In summary, this dynamical model accounts for a number of post-Newtonian perturbations in the motions of the planets, the Moon, and spacecraft. Light propagation is correct to order c^-2. The equations of motion of extended celestial bodies are valid to order c^-4. Indeed, this dynamical model has been good enough to perform tests of general relativity @28,51,52#."

I'd comment that if you read and understand the entire paper, you're well on your way to really knowing how we do deep space navigation and the myriad things that have an effect and must be taken into account. They also have a VERY complete discussion of numerical computation effects.

They also do mention an annual sinusoid (not accounted for by simple orbital motion) of 1.6E-8 cm/s^2... (about 0.012 Hz at 2.29GHz) (page 37) which they attribute to small problems in their modeling of the solar system that are normally masked by other noise sources, but because Pioneer makes such a good detector, you can find it.

I'll note that the anomaly identified in the paper has since been analyzed extensively, and as I recall, once you take into account the thermal radiation pressure with sufficient accuracy, you can account for it.

(there has been a substantial improvement in computational and modeling capability in the last 10 years, since that paper was published) After all, the paper says "Further experiment and analysis is obviously needed to resolve this problem."

They wrote (page 37): "
Fig. 17, which shows the aP residuals from a value for aP of

(7.7760.16)31028 cm/s2. The data was processed using

ODP-SIGMA with a batch-sequential filter and smoothing algorithm.

The solution for aP was obtained using 1-day batch

sizes. Also shown are the maneuver times. At early times the

annual term is largest. During Interval II, the interval of the

large spin-rate change anomaly, coherent oscillation is lost.

During Interval III the oscillation is smaller and begins to die"

I "read the entire paper" but I do not and understand if the above "During Interval III the oscillation is smaller and begins to die" means that the annual variation in frequency die when the spacecraft was very far.

I was ony trying to pick up if the annual variation in frequency take place or not.

The reason is simply. The diurnal variation are in agreement with the Michelson-Gale experiment. The annuall should be null like the famous MM.

I imagine so, although I don't know where one get the data off hand.
But they archive and publish pretty much everything that comes down
along with all the radiometric data (doppler, phase, signal strength) in
various and sundry mission data repositories. getting it in a
convenient translated form might take some work.

Look for what's called Level 0 telemetry data from your missions of choice.

Dunno..

>
> I was ony trying to pick up if the annual variation in frequency take place
> or not.

The "anomaly" variation or the "variation due to earth in its orbit"? I
suppose the answer to both is "yes"

>
> The reason is simply. The diurnal variation are in agreement with the
> Michelson-Gale experiment. The annuall should be null like the famous MM.

If you need raw data, you'll need to look for it. I'd suggest starting
with the Planetary Data System http://pds.jpl.nasa.gov/

Maybe the stuff at NAIF (Navigation and Ancillary Information Facility)
might help.

There's a lot of stuff out there, but, for instance, I ran across the
raw Radio Occultation Original Data Records from Ulysses. It has a
description including: "These data are
obtained from the Radio Science Support group at JPL. They consist
of time-ordered, high-time resolution Doppler data from special
radio science receivers (so-called 'open loop' data)."

There's a lot more description online and that's probably not a data set
you're looking for, but the data is out there, if you're willing to go
digging through it. I doubt anyone is going to give you exactly what
you're looking for, though. You'll have to do some conversion, and
you'll need to know a fair amount about how all the tracking systems
work, but that's all published. You might start with the DSN 810-005
online document (google for it).. That will tell you how they record the
data and the format.

A more recent data set is from MRO
"This data set contains archival raw, partially processed, and
ancillary/supporting radio science data acquired during the Mars
Reconnaissance Orbiter (MRO) mission. The radio observations were
carried out using the MRO spacecraft and Earth-based receiving stations
of the NASA Deep Space Network (DSN). The data set was designed
primarily to support generation of high-resolution gravity field models
for Mars and secondarily for estimating density and structure of the
Mars atmosphere. Of most interest are likely to be the Orbit Data Files
and Radio Science Receiver files in the ODF and RSR directories,
respectively, which provided the raw input to gravity and atmospheric
investigations, as well as the ionospheric and tropospheric media
calibration files in the ION and TRO directories, respectively."

http://starbrite.jpl.nasa.gov/pds/viewProfile.jsp?dsid=MRO-M-RSS-1-MAGR-V1.0

Among the stuff in that particular data set is:
" The ODF is a compressed version of the TNF. It contains the most
important information (range, Doppler and frequency ramps)
needed by spacecraft investigators, and investigators interested
in determining gravity fields. Each ODF is accompanied by a full
PDS label which describes both the content and format of the
associated file. ODF data fields include:

Narrowband spacecraft VLBI, Doppler mode (cycles)
Narrowband spacecraft VLBI, phase mode (cycles)
Narrowband quasar VLBI, Doppler mode (cycles)
Narrowband quasar VLBI, phase mode (cycles)
Wideband spacecraft VLBI (nanoseconds)
Wideband quasar VLBI (nanoseconds)
One-way Doppler (Hertz)
Two-way Doppler (Hertz)
Three-way Doppler (Hertz)
One-way total count phase (cycles)
Two-way total count phase (cycles)
Three-way total count phase (cycles)
PRA planetary operational discrete spectrum range (range
units)
SRA planetary operational discrete spectrum range (range
units)
RE(GSTDN) range (nanoseconds)
Azimuth angle (degrees)
Elevation angle (degrees)
Hour angle (degrees)
Declination angle (degrees)
"

So there you have all the VLBI and doppler info you're looking for.

The actual data files are at
http://pds-geosciences.wustl.edu/mro/mro-m-rss-1-magr-v1/mrors_0xxx/
(There's a link at the PDS catalog entry)

There's documentation on the format of the ODF files, and I see that
they actually give you Doppler and range observables, rather than raw
counts, which is nice.

Knock yourself out...

They confirm the diurnal oscilations.
They do not mention the annual.
So I assume that the annual are null.

The answer I am loking for is not important for me.
I have come accros an information that astronomers add the orbital speed of
the Earth to the radial speed of stars measured with the spectrographic
method.
The radio method are the same like the spectrography. But it contradicts
MMX. So I am trying to clear it.

Uh.. no.. you have a theory or question, but aren't willing or able to
do the work (or find someone else to do the work) to actual resolve the
issue.

Tons of data
Tons of analysis out there

You've got a question, you need to answer it.
(or, just wait until someone else happens to answer it for you...)

Yes. I am not able.
But here is nothing to do. Some people know the Doppler effects components:
"the Doppler has several components: one from the rotation of Earth, one
from the rotation of Mars (for a surface asset), and one from the relative
motion of Mars and Earth"

I am looking for information about relative motion of "Mars and Earth" and
"Earth and Pioneer".

"wait until someone else happens to answer it for you..." is the only possibility.

Sooner or later it will be in textbooks.

Now in textbooks no Michelson-Gale experiment.

You sound like the man in the street who claims that "the theory of
relativity is wrong".
But in your case you don't even refer to something as complex as
relativity but as simple as doppler shift.

There are existing formulas that allow you to calculate the doppler
shift when knowing the speed of the items, and the measured results
confirm what you calculate. So why do you keep questioning it?

When you have found an old article that does not agree with what is
measured today, why do you keep insisting that the old article is
correct and suggeest the theory is wrong, when you don't have the
capability to back that up with proofs that you present yourself?
Isn't it better to assume that the measurements in the old article were
not correct?

It is true for the Earth rotating.
For the orbital movement of the Earth the result is null according to "the
theory of relativity".
>

> not correct?

In physics textbooks the old article is correct.

Once more: "Today's spectrograph astronomers assume that the effect is not
null.

It seems to me that today's astronomers are wrong because in physics are
still null result.
So I am looking for the result from communication with the spacecraft."

I should wrote: "Some astronomers ASSUME..."

To be precise now are available the spectrograph with built-in the
corrections for the all movements of the Earth and Sun.
But user can switch off same of them.
It seems to me that at measurements of the radial speeds of stars the
correction for the orbital speed of the Earth should be switched-off.

What is your opinion?

Not the case.

In 1905 Einstein wrote: "Examples of a similar kind, as well as the
unsuccessful attempts to substantiate the motion of the earth relative to
the "light-medium", ..."

It is still valid. One of the attempts was famous MM.

In 1925 Michelson-Gale "substantiate the motion of the earth ROTATION
relative to the "light-medium". It is in agreement with SR. (Like Sagnac).

But things are changing. May be that the attempts with using the radio waves
supply the opposite results. But I do not come across on such.
So I am asking the radio experts.

I recently came across some JB Weld Waterweld and Loctite repair putty. I have used this two part hand moldable epoxy for various indoor projects and have met with success on a number of occasions. I am now preparing to erect a dipole and I am wondering how well this epoxy would work for the center/ end insulators? My main concerns are UV, weathering and of course longitudinal strength. Anyone have experiences/ recommendations they can share?

Thank you.

I'm not familiar with these specific products, but I know
from experience the standard JB Weld is conductive. Not a
good choice for repairing insulated parts.

I thought that one of the parts had some powdered steel or something in it.
Anyway....make a sample and test it in the microwave.

No, according to their website, standard JB Weld and Waterweld are nonconductive. I have some hardened Waterweld here that I just tested with the ohmeter and there is no conductivity. They do have a steel reinforced one thought that would be conductive I suspect.

Why would I want to test this stuff in the microwave?

Dielectric losses.

Make sure you have a cup of water in there while you do
it. But afterwards check the blob of material to make
sure it stayed at room temperature.

Remember that testing with an ohm meter is testing at DC. RF wise, it might be a different story.

Regardless of matters of conductivity, insulators are cheap enough that they would be a better choice than repairing a broken insulator. I'd be very skeptical of the structural integrity of such a repair, especially if the break was not caused by impact. That would mean that the break was caused by structural stresses, and would likely recur.

Thanks to all. I decided not to use the Waterweld due to the uncertainties. I tried to use what coax seal I had left since Radio Shack no longer sells it and I lacked time to get more, so what coax seal didn't seal I covered with electrical tape followed by a couple of coats of liquid electrical tape.

I think my original question here was a little misleading. I really wasn't needing a support insulator, but a proper seal. I was building a folded gain dipole for 20 meters out of 300 ohm twin lead, so the ends had to be sealed as well as the two center places where the beams connect. Hard to explain, but I sealed as above. Hope it holds up.

You can put several coats of "Liquid electrical tape" over the
connections. That's flexible and water proof.

OK, good luck.

But, I was hoping to see someone microwave test the JB. Might do it myself,
just out of curiosity if I get tired of watching the squirrels run up and
down the tree out back :)

2712. Satellite Direction Finding?

Newsgroup: rec.radio.amateur.antenna
Date: 2011-11-26 02:42:39 UTC
From: "Leland C. Scott" <kc8ldo@arrl.net>
Message-ID: <qaSdnT-7d9yFz03TnZ2dnUVZ_q6dnZ2d@giganews.com>
Source record: 3313

From time to time I've read about some interference, or deliberate jamming, of an amateur satellite.

My question is has anybody written a nice paper where using known orbital elements of the satellite and Doppler Shift to calculate a curve on the earth's surface where the source maybe located? I would think any issue with the satellite's transponder's frequency conversation, due to local oscillator frequency drift, can be corrected for by calibrating the link between two or more known stations. This I'm assuming would likely only work for linear transponders.

Since the satellites are in highly elliptical orbits the Doppler Shift would be different over several orbits. Then using multiple orbits these curves I think would tend to intersect, or nearly so, at one point. Additionally the time of signal acquisition and loss can be timed and compared to the projected ground foot print of the satellite coverage zone to help zero in on the source location.

Sorta. That's how the Transit (NAVSAT) satellite navigation system
worked, but backwards. In the Transit system, the ground station
measured the doppler shift from the satellites. In your case, you'll
need to measure the doppler shift of the ground station from the
satellite. That's going to be difficult because your ground station
will have both the ground to satellite doppler, and the satellite to
your receiver doppler to deal with simultaneously. Since both the
postion of the satellite and your station is known, the 2nd doppler
shift can be calculated. Note that the only part of the "S" curve
that's really important is where the satellite passes overhead. A
highly elliptical orbit will make that somewhat tricky.

The math to recover the first doppler shift involves an exercise in 3D
spherical geometry, which is non-trivial. I'm not even sure I could
still do the math. Sorry no software handy:

Correct. The "bent pipe" satellite transponder is the only one that
will pass the uplink doppler shift. It won't work with a
demodulate-remodulate repeater.

Yep, except that from 100 miles up, the "cocked hat" pattern formed by
the lines of position is going to be rather large. I don't have a
feel for the expected accuracy, but I'll guess(tm) that you'll be
lucky if you can locate anything within a mile radius.

Good luck.

It should not be difficult to locate the source so accurately that you could go to that position and hear the transmitter and locate it using land-based direction finding.

However, this usually is not very practical. The interference comes from countries with little amateur activity, and who wants to go there for a fox-hunt (which you maybe cannot start right away, you have to wait until the interfering transmitter is active again).

And then, what are you going to do once the source has been located? The local authorities are probably not that interested in getting it off the air...

Check eBay.

Don't know about the 745 but I see auctions for IC-735 parts or entire
735's for parts.

2720. Stub J-pole for six meters

Newsgroup: rec.radio.amateur.antenna
Date: 2011-11-26 22:22:52 UTC
From: Tom Horne <hornetd@gmail.com>
Message-ID: <8b22e1d5-907a-4ee6-ab40-4c3333231ab7@o13g2000vbo.googlegroups.com>
Source record: 3321

Can anyone direct me to the dimensions to build a six meter J-pole that is patterned after the Arrow Antenna two meter design that had the feed point at the bottom of one of the elements rather than at a point part way up the height of the matching stub.

The reason that I would like to use that design is that I would like to use Rigid Aluminum Conduit to build the antenna. There not being a lot of simple inexpensive fittings for Conduit the way there is for copper pipe a mechanically simpler design would be easier to build.

Replies are welcome on or off list. Let me say that I would rather not be subjected to any tirades about the inferiority of the J-pole approach or the superiority of some other antenna design. That does not mean that I am not open to suggestions for a better approach as long as it is civilly stated and I am spared the application of Rant Mode.

From: Radiohouse <radiohouse@nowhere.net>
Message-ID: <jarue1khv1@dont-email.me>
Source record: 3322

Just put up a 80 meter dipole today, but had some difficulty with two things: proper tying off of the lift/ support rope and proper tying off of the guys. When I say "support rope" here's what I mean: one side of the dipole was anchored high in a tree while the other from a 30' telephone pole. The tree had a pulley installed, so the "support rope" hangs down from there as well as the eye bolt from the telephone pole (support rope through the eye bolt). So, I'm not sure where or how to tie the support rope ends. Right now, on the tree side, I just have several turns around a low branch with a knot; basically the same with the telephone pole side. What is the proper way to secure the base of the supoort rope?

How do I tie the guy wires?

Thanks for any help.

It is a sad statement of the state of affairs when you feel a need to compose a help request with such conditions, 40% of your post is setting conditions on your would be helpers responses.

This is not unusualy, the posts can often can be paraphrased as "I have got this really good idea, and I don't want to hear from anyone that it is less than a really good idea... over".

Your 40% conditions is by no means a record, higher percentages have been observed on QRZ and eHam, such high percentage as to make the whole thing look like a troll rather than a genuine request for help.

My own view is that it helps to be a little humble when seeking help.

Owen

The 144/440 antenna can be found at:
<http://www.arrowantennas.com/inst/OSJ146440.pdf>
with dimensions included. You probably won't need the short element
in the middle which seems to do something for 440Mhz operation.

Two ways to do this:
1. Plug the dimensions (in wavelengths) into an EZNec or 4NEC2
antenna model, and scale it for 52MHz.
2. Scale the antenna dimensions linearly from 146 to 52MHz and
optimize with cut-n-try. The driven element is 1/4 wavelength long,
and the parasitic element is 3/4 wavelength long.

>The reason that I would like to use that design is that I would like
>to use Rigid Aluminum Conduit to build the antenna. There not being a

Maybe, but the 3/4 wavelength element is going to end up about 15ft
long, which is rather long for tubing without a top support. The
"rigid" aluminum conduit is made to be bent to shape. I suspect this
15ft long tube might deform in the wind.

>Let me say that I would rather
>not be subjected to any tirades about the inferiority of the J-pole
>approach or the superiority of some other antenna design.

Ok. I'll just ignore my experience with J-poles and pretend that
they're suitable for your unstated purpose.

>That does
>not mean that I am not open to suggestions for a better approach as
>long as it is civilly stated and I am spared the application of Rant
>Mode.

Approach for what application and mounting? If you want an antenna
with a rather high takeoff angle, an end fed antenna, such as the
J-pole will send most of your RF towards the birds instead of the
horizon. If you want an antenna with a radiating coax cable (by
lacking a balun), the J-pole is quite appropriate. If you want an

antenna that produces impressive cloverleaf horizontal gain patterns when side mounted on a tower, the J-pole is the hot ticket. The J-pole does have one big advantage. It was originally called a Zepp antenna, after the Zepplin airship, where the antenna was suspended downward. Because the low voltage point is at the base of the antenna, there would be no sparks to ignite the hydrogen gas. However, if you don't plan on flying your j-pole on a Zepplin, this advantage might not be very useful.
<http://en.wikipedia.org/wiki/J-pole_antenna> (first paragraph)

Please feel free to offer undying praise and monetary renumeration for the advice. I'm always open to being paid. There are probably better designs but since you've already decided on a J-pole, it's probably futile to suggest alternatives. Besides, it might precipitate a debate or arguement. Oddly, I learn more from such debates and arguments, than from pontifications.

5/8 wave 6m ground plane:
<http://802.11junk.com/jeffl/antennas/gnd-plane-02/index.html>
5/8 + 5/8 wave 6m ground plane:
<http://802.11junk.com/jeffl/antennas/gnd-plane-05/index.html>

I would normally offer to build you a NEC2 model of your proposed antenna, but since I don't know what diameter aluminum tubing you have in mind, and since it's 1:30AM, I'll pass for tonite.

Certainly not a rant but a question about the question:

Is your reason for this approach mainly your access to beaucoup aluminum conduit? I ask because I'm a j-pole fan and I've built dozens of them, including three for 6m using copper pipe and one 6m from window line. The feed is less than 7 inches from the bottom of the active portion of the 6m version.

Using your conduit, you might employ the "standard" j-pole design and bolt the segments together, placing wooden dowels inside your conduit ends to resist crushing forces. Am I striking a chord, yet?

A brace near the top of the stub section would likely be required to prevent rotation where the bottom of the "j" attaches to the main section. You might be well-served to wrap the bottom of the "j" with a tight spiral of mesh sleeve (like the braid-only of some unneeded coax) and clamp the ends. This would help mitigate the electrical consequences of a bad joint or two. Alternatively, bridge (jumper) the individual joints.

But see http://www.wagnercompanies.com/cast_aluminum.aspx , where a single 3/4 - inch tee or elbow is about $7.00. Do-able?

Note, my 6m copper j-poles are all 3/4 - inch material except the top three feet of of the long section. I tried using all 1/2 - inch copper once but

that build was so wobbly that I immediately took it apart. (It's about 13 feet tall.)

Some of my j-poles have benefitted from having a capacitor from the feed connector center pin over to the the long side, in lieu of a straight piece of wire. I use one whenever the VSWR is mid-band but above 1:1. No science to it; I just tried a few around 100pF and SHAZAM! I was inspired by the capacitive feed in a gamma match.

Happy brewing.

Some people use gravity in the form of a bucket with rocks or scrap
concrete. It takes up slack (or pays out) as dictated the wind or ice load
on the antenna.
>
> How do I tie the guy wires?

Clarify guy wires, please. I have three dipoles, none with guy wires.

I have finished two tutorials on noise.

the first one is here:

http://www.fourier-series.com/Noise/index.html

This covers thermal noise, and contains several interactive flash programs. included is insight into the thermal noise equation, rms voltage calculations, examples of correlation and how independent (uncorrelated) noise adds together. All the programs have extensive audio explanations.

The second one is here:

http://www.fourier-series.com/Noise/NoiseFigure.html

This covers The basic noise model of an amplifier. Spectrum analyzer representations of input signal and noise and output signal and noise are presented with interactive features to allow the user to modify signal levels, gain and noise figures of the amplifier. A full explanation of the noise factor model and derivation of Friis formula using interactive programs and audio explanations are provided.

Yes. Look for papers on the Argos system (that's what they use for
tracking things like buoys, etc.).

Here's some starting points:
3 papers by Levanon, et. al.
1985 Random Error in ARGOS and SARSAT Satellite Positioning Systems
1984 Theoretical Bounds on Random Errors in Satellite Doppler Navigation
1983 Angle-Independent Doppler Velocity Measurement

More recently
2007 Amiri & Mehdipour, "Accurate Doppler Frequency Shift Estimation for
any Satellite Orbit"
2008 Amar & Weiss, "Localization of Narrowband Radio Emitters Based on
Doppler Frequency Shifts"

I would think any issue with
> the satellite's transponder's frequency conversation, due to local
> oscillator frequency drift, can be corrected for by calibrating the link
> between two or more known stations. This I'm assuming would likely only work
> for linear transponders.

Actually, you don't even need that. If you think about it, what you are
trying to do is do a sort of curve fit where the unknowns are the 6
orbital elements and the frequency of the transmitter.

Simple techniques (like those you'll find in the Satellite
Experimenter's Handbook and similar works) tend to focus on things like
determining the inflection point of the Doppler curve, which tells you
the point of closest approach, and then relating that to figure out the
orbit (or position of the receiver/transmitter).

before the advent of the computational horsepower, analytical techniques
like this were popular. You could do fixes and orbit determination with
a stopwatch and slide rule.

Much like doing Celestial Navigation using Nautical Almanac and sight
reduction tables vs using a computer.

These days, iterative approaches are more useful, and have the advantage
that you can weight the individual observations by their SNR, for instance.

>
>
>
> Since the satellites are in highly elliptical orbits the Doppler Shift would
> be different over several orbits. Then using multiple orbits these curves I
> think would tend to intersect, or nearly so, at one point.

Yes. It depends on the orbit. Some are more useful than others, i.e.
the classic 4 day repeat frozen orbit only gives you half a dozen
different paths over any given point on the surface.

Additionally the
> time of signal acquisition and loss can be timed and compared to the
> projected ground foot print of the satellite coverage zone to help zero in
> on the source location.

It's fairly straightforward, and if you think in terms of iterative
solutions, all you really need is a decent goal-seeker/optimizer engine
tied to a orbit simulator. There's a variety of Matlab/Octave packages
out there that do the orbit mechanics, and likewise, there's optimizer
engines.

For that matter, doing the orbital stuff yourself isn't that hard with
matlab/octave/mathematica or even C, BASIC, or PASCAL. Especially if you
don't need gnat's eyelash precision. Take a look at the MIT
OpenCourseWare offering for 16.07 Dynamics Fall 2008 Version 2.0 by
Widnall and Peraire.. Specifically Lectures 15 and 16

T.S. Kelso's SGP from the celestrak.com website is a defacto standard
orbit propagator. There's tons of implementations out there in pretty
much any language you want.

Actually, you really need to see as much of the curve as possible.
Sure, just knowing point of closes approach (center of the S) is
commonly used in navigation solutions, but seeing the whole curve lets
you take out more of the unknowns.

One assumption is that the frequency of the oscillator is "reasonably"
stable over the observation time (100-1000 seconds for most LEO) so that
the frequency measurements have low variance, and that the drift is
small. Crummy RC oscillator with tons of phase noise wouldn't help.

160km is VERY low for an orbit (that's Phoebus-Grunt kind of territory)
ISS is low (350-400 km) and has significant effects from drag. Most
LEO are at 600km and above.

Locating to within a mile should be straightforward. ARGOS regularly
gives positions of wildlife trackers and such to about 500m kinds of
accuracy.

Because they're selling wire for antennas, which is supposed to be
hard-drawn?

It's an absolute bugger to get 6 trifilar turns of
> hard drawn #14 wire onto a 1.5" OD toroid. It would be much easier,

For coils, as you note, you want soft annealed. If your core is big
enough, you can use ordinary THHN house wire.

Owen

I apologize for coming across as arrogant. I didn't mean to.

Perhaps it would help to know that I was looking at the J-pole as a
transportable antenna that would be used when the operating position
is down in between buildings, ridges, mountains, etc. I did look at
the online patterns for a J-pole. When I used a diamond ground plane
under those conditions the results were less than satisfactory. The
intent is to get the signals up out of the hole. The aluminum conduit
was because it is much lighter than copper pipe and far less expensive
at present pricing. I may want to replicate the antenna several times
if it happens to overcome the problem for the purpose of reliable
communications outside of simplex two meter range without limiting the
operator pool to general and above licensees. Also there are several
places were we could use six meter APRS to collect data from, for just

example, a temporary stream gauge by installing the gauge in the time between a flash flood watch and any subsequent flash flood warning. Obviously the temporary gauging point may well contribute to the decision as to whether and when to issue the warning. I was thinking to use rigid aluminum conduit because of the availability of both compression and threaded couplings. I intended to test which coupling technique would stand the most bending force on the upper portion of the antenna. I already guessed that the antenna might need to be guyed but I wanted to try whether using a one inch or even one and a quarter inch nominal size would avoid the need for that. Since the Arrow Antenna design is fed at the bottom of the shorter matching stub I thought it might be easier to transport and deploy without damaging it. As for keeping the stub in line with the radiator I had envisioned a short piece of 5/8" fiberglass U channel with two stainless steel pipe clamps as being robust enough to withstand repeated handling. The three quarter wavelength portion of the antenna would be fashioned into three nearly equal sized sections for ease of transport.

I have constructed a dual half wave collinear J-pole using copper pipe. It had given me much better empirical performance than the borrowed ground plane that I had used before it. If I could get the needed range out of the simple J-pole I was next going to work on the physical challenge of building another collinear dual half wave for six meters were the second have wave could be added readily for use when the antenna would not be located below local horizon.

If you have not found anything by now, you may go here for a 2 meter
version. Then divide the 150 mhz frequency by the 50 mhz frequency and get
a number near 3. Then multiply ALL the dimensions by that number. That is
the lengths, diameter of the elements and spacing.

All hands

Let me start over. I want a transportable, six meter, vertically
polarized antenna. The parts have to be readily assembled &
disassembled. I would like it to have a somewhat higher than normally
attempted radiation pattern for use between buildings, hills,
ridges... [I had thought that a J-pole might be a good compromise
instead of antennas with a more horizontal gain pattern.] It would be
really golden if the adding of additional parts would change the
pattern back towards the horizontal to use the antenna when it is
located above local horizon. Parts should be short enough to fit in
the foot well of the back seat of an ordinary sedan. It's a stretch
but If it did not need guying that would contribute to ease of
deployment especially in an urban operating location were the
anchoring possibilities for guy lines may be limited. [I'm trying to

devise an X frame tripod. It would be made out of fiberglass structural channel in order to lower the weight of the tripod assembly but that is not an antenna design problem.] I may need the antenna to be elevated when operating near pedestrian traffic to reduce the risk of RF contact or excessive exposure. Shielding the feed point from physical damage; such as by having it inside a piece of Box channel would be quite desirable. I'll leave it there and see what folks can think of that might work.

Tom,
how concerned are you about the "match"? What length of coax are you
feeding it with? Do you care if the coax radiates? What bandwidth do
you need? (fat elements have broader bandwidth, for instance). How
rugged does it need to be?

You're looking at something with an overall length around 3 meters/10 feet?

If the j-pole is being done so you have a mechanical support, there are
other ways to approach the problem. I assume you want something that is
"feedline comes out at the bottom", so why not something like a dipole
with the feedline going up inside the bottom half of the dipole? You'd
need something mechanically strong enough to hold the two pieces of
aluminum together that's an insulator. Hose clamps would work to both
make the wiring connection and hold the tubing to the insulator. (I'd

look at a piece of fiberglass or plastic rod of appropriate diameter.)
Since you want to use conduit kinds of things, what about using standard
plastic electrical things. Perhaps a plastic conduit outlet body?
(Cantex PVC conduit body, type C, 1/2" hub, Grainger part #4FYP5, about $5)

Just screw the threaded end of the conduit into the body and you're
done. (If you get the stuff with a removable coupling, especially easy..
10ft stick, saw it in half, and you're almost done)

Do you have test equipment for tuning? Or are you looking for a
cookbook design that you can just build and know it will work as long as
the dimensions match the recipe?

Tom,

The clever thing with the Arrow implementation is its dual band version where it is mechanically elegant. Does it lend itself to scaling up by near three times?

It isn't clear that you wanted a dual band version, though there are hints.

If you are looking for a single band antenna as implied in the subject...

As you have noted, the total height of the J pole for 6m is a potential issue.

You could look at it as essentially an end fed half wave with a rather large impedance matching device (~1.5m).

There are other more compact ways to impedance match an end fed half wave. The question for you is whether you can devise a robust implementation.

Is there advantage in using aluminium tube over wire? Well, obviously the wire needs support, but perhaps a telescoping fibreglass pole and wire with a matching network in a PVC box is another robust option.

Keep in mind that end feeding a half wave reduces the common mode current flowing to the feedline, the feed point voltage is highest at exactly a half wave. You might find a slightly shorter radiator to deliver most of the 'ground independent' feed, but with slightly less demands on the voltage rating of the matching network. It may be prudent to make your matching network adjustable to provide for locations where proximity to other things changes the tuning.

I said fibreglass (meaning literally glass reinforced plastic), and that doesn't include graphite or carbon fibre. A lot of these fishing poles are now made from graphite, and that introduces potential for loss.

BTW, I am not sure that your 'design' of the pattern is all that sound, however real antennas near lossy soil just don't have very low angle major lobes... so what you want happens for probably any low makeshift antenna.

Owen

The love-hate relationship with J-poles has been pretty well
documented over the years here on r.r.a.a. My feeling is that you can
resolve that pretty well by decoupling the antenna from the feedline,
and also from other nearby conductors. That's something you want to
do with any antenna, at least where you want to have consistent,
reliable performance in the face of differing feedline and antenna-
support installations. One of the implications here is that you'll
have a non-conductive support for the antenna. You should be able to
get pretty reliable feedline decoupling with a choke in the feedline
where it drops below the antenna, and another a quarter wave below

that. For narrow-band operation (say operation in a band less than 1MHz wide at 50MHz), I'm partial to tuned chokes: a small coil of coax bridged by a capacitor to resonate it at the operating frequency. That's obviously not the only way to do it, but done right, it can give you quite a high impedance in series with the line while adding negligible additional loss due to the slightly longer feedline.

Since a J-pole is nominally 3/4 wave long, at 6 meters wavelength that implies something roughly 4.5 meters, or about 14 feet, long. I guess you can come up with some arrangement of pipes that will fit across the back seat of your car that you can put together to get what you want, maybe four nominally 1/4 wave sections. I wonder, though, if it wouldn't be easier to use telescoping sections of fiberglass (or similar reasonably stiff mast material) that would take you up to where the top of the antenna needs to be, and then just use a wire antenna. Then if there happens to be a natural way to hang the antenna (e.g. from a line tossed over a tree limb), you don't need to bother with setting up any mast + support.

As far as exact dimensions of the antenna itself, given all the good antenna analysis programs out there, I consider that the easy part, but dependent on just how you elect to make it: wire or sections of conductive tubing, and just how you will feed the antenna (tapped up the shorted quarter wave bottom section, or connected to the open bottom of the quarter wave). Pick a mechanical arrangement that works for you, then use a program to come close to the required feed arrangement and details of the element lengths and spacing, then build/measure/trim to get what you want -- if you accept that anything below a 1.5:1 SWR works well, then you will probably have little if any trimming to do, assuming you modeled it accurately.

Cheers,
Tom

2740. Help on Severns equations

Newsgroup: rec.radio.amateur.antenna

There is table of measured values for R and X on page 10.
Just plug them into the formulas on page 9 and see if you come
up with the same answer for the equations in (1) and (2)

For R = 129 and X = -134

R^2 = 16641
X^2 = 17956
R^2 + X^2 = 34597
R/(R^2 + X^2) = 129/(16641 + 17956) = 129/34597 = 0.0037286
8.84 * 0.0037286 = 0.032961
0.032961 / 7.41 = 0.0044482

Side Note: in the 25 years I worked in the aerospace industry
in Southern California, I ended up chasing Rudy back and forth
across several employers. I finally had the pleasure of meeting
him face to face around 1987.

One of the more interesting things he told me, "When doing your
resume, highlight your accomplishments and gloss over the
aberrations."

Regarding the higher than normal angle request, either

1) make it fairly short so as to approximate an isotropic radiator

2) make it a significant amount longer than a normal J pole so you get
lobes above the horizon. You will need to model this for each concrete
or natural canyon you expect to be in.

And then think a lot more. Possibly a different solution is better.
Different band to start with. I don't know, just trying to stir up your
thinking.

Basically, however you have to, or can. There's not just 'one way' to do it, it's whatever 'fits' your particular situation. If there's much wind, and if using trees for supports (for example), it's a good idea to 'allow' for some movement (as Sal said). A bucket of rocks, a bungee cord, or tarp strap can work.

I use polyester dacron antenna rope. Guy wires are impractical for your application. The dacron will try to untie itself, so flatten the knot with some PVC tape to keep it from unraveling. The tree end needs a short rope with a pulley, and a counterweight on your main antenna rope. Who owns the utility pole?

> > How do I tie the guy wires?

Hey OM:

I see you has 2 postings here both referring to guy.

At work on the great lakes shipping my foreman always called me guy.
He would say hey guy do this or that. So my question are those my
wires?
That you call guy?
I would use guy ropes rather than guy wire. although you can use wire
but you better has broken it up into lots of pieces.
so they doesn't resonate on the band you are operating on.

I know, off topic but I do get good advice from this group. I will take the mud slinging,,, hope it is mixed in with your regular good information.

I have a back yard garden, I live in Southern Ontario Canada. I roto till it and we grow vegetables like tomato, peppers,

My friends were telling me I should mix in some leaves, my garden is about 20 feet by 20 feet.

I collected about 50 big bags of grinded up leaves and roto tilled them all into my garden. Very light and fluffy now and soft and full of broken down leaves, mostly Maple Leafs and some other varieties.

My question is what should I do? Should I mix in manuer? or furtalizer? Should I do something with this mixture now? Will it be ok on its own after a few years ? will these leaves breakdown on their own? should I put more leaves in? I think 50 bags is a lot.

Any advice or tips is much appreciated. Thank you 73s

You might want to check with the good folks over at
rec.gardens.edible.
What I do is to leave the leaves on the garden untilled
as mulch. In the spring I will roto-till them in.
Let them sit for a few weeks, then test the soil to
see if any amendments are needed.

Compost. It's one of the best "soil amendments" you can have. A composter can be built for a few dollars but you have to attend to it with moisture, aeration and/or tumbling. Google for "homemade composter" and see what others have built. Properly composted material will resemble ashes or dirt, depending on the texture of your source plants.

The leaves will eventually break down on their own and sort of "self-compost" but you can speed the process with a little work. Mix in the compost and it replaces some fertilizers.

Garden centers all sell soil test kits. The results of a test will suggest whether you need supplimental fertilizers.

Manure can be acidic and may do more harm than good. If you compost it, too, it will be less acidic.

Sal

As one other poster suggested, check with your local agri-support folks. I'm from northern NY, FN24, and moved straight west to MN, EN34. When you are this far north you need to know exactly what climate range you are in, and then assume it's a half point to a point worse. Then your plants will usually survive.

You are probably a fraction of a climate zone north of me unless you are tucked in between the ends of Erie and Ontario.

URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team had decided to consider |
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. After a successful trial |
period (90 days, through early July 2009), we decided to adopt this |
change permanently. |

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.

The breakdown of leaves is a dfferent process than that of making compost
and takes a lot longer. You should not add leaves to you soil but in time
the worms will eat it all up.

Use the leaves to make leaf ulch which you can then use on the surface, see
http://www.hereandthere.org/making-mulch/making-mulch-from-leaves.html

Charlie.

I'm posting this for a buddy of mine who can't get newsgroups on his system..

This is an OLD mint portable battery pack, model number HB-506. This is for the HB-525 / 625 radios of the late 1960s.

http://www.ebay.com/itm/130609760136

go to ebay and copy and paste the item number if the link does not work

Yes, thanks all hams, yes, excellent advice.

I don't want to put in a composting pile as I feel that might attract a lot of mice or animals as my neighbors have told me. I know the pile of leaves gets warm in the middle. One neighbor told me about nitrogen, my situation required nitrogen and the region here has a byproduct from our waste and they call it bio wastes and the farmers line up apparently for it. He said he can give me a couple pails but he says it is very potent or almost 95% nitrogen. And he says the ministry of environment wants to know about it and fill out a bunch of forms.
I like the idea of a composter, easy to do, looks managable. Thanks again hams for the great advice. I know it is off topic but as I said, I get a lot of good advice from this group, the gardening groups are not active or attached to my news server. Much appreciated.

73s and happy holidays

Turn it when it starts to get warm or you may end up with an ash pile.
Any green waste (no sticks) will feed it. I used neighbors' lawn
trimmings and leaves. I never needed any extra boosters. Only critters
you get is earthworms. Their poop is the fertilizer. I think the nitrate
may inhibit earthworms. Earthworm casting is the fertilizer you get from
a succesful compost situation. Build in on the ground.

2762. Feedline suggestions?

Newsgroup: rec.radio.amateur.antenna
Date: 2011-12-05 17:01:15 UTC
From: Wayne <mygarbagecan@verizon.net>
Message-ID: <jbiti4$j2d$1@dont-email.me>
Source record: 3263

I am using a whip antenna mounted on a metal patio cover. Results are good on 10 and 12 meters, and contacts have been made down to 40 meters. (Matches were not obtained on 15 or 30 meters) The whip is 8.5 ft long (a longer whip is under consideration). It is fed through an antenna tuner and about 25 feet of RG-58. I'm about to replace that with RG-8.

Any comments on how to hold down feedline losses. One suggestion is to use two parallel lengths of RG-8 so that half the current runs through each. Also, site geometry would allow open wire feed.

Possibilities?

Sorry, Parallel cables would give you twice the losses. Also, what it
would do for matching will vary by frequency but not likely anything
you want. Lower loss coax is always a good idea but with only 25 feet
total your losses may not be enough to notice. Vertical antennas are
usually at their best at 1/4 wave length long for the purpose of
radiation. In practice, if you get it tuned up well enough to take
power, it will work!

I have a 28 foot vertical antenna that sometimes outperfoms my 3
element beam. It is tuned with an SGC autotuner.

There is a lot of information on the internet for free, Google a bit
and keep at it. I seem to enjoy working on antennas more than using
them.

BTW, Check out the ARRL.NET site. There is a 10 meter contest in a
week or so that your antenna will around the world...

I use screen-door spring(s) at each end of my wire antennas to permit tree/limb movement without stretching the antennas. You should be able to buy such springs in several strengths at 'most any hardware store (probably even WalMart or K-Mart) in the USA. If I think one spring might not be strong enough for a particularly-heavy antenna, I just parallel two springs.

Of course, the springs are between the antenna insulators and the ropes used to pull/tighten the antennas.

If you do use weighted buckets, be sure to tie ANOTHER rope to the bucket and a nearby limb so the bucket won't fall on someone's head if the antenna rope or wire breaks!

As John mentioned, 25 feet of coax is too low of a loss to worry about
especially below 30 Mhz. The other best bet is to use a remote antenna
tuner at the antenna. A longer antenna should work much beter on 80 and 40
meters.

Dear Wayne (no call sign given): The use of "it" causes an ambiguity. If the antenna tuner is "at" the antenna feed point, then 25 feet of RG-58 running to the shack will contribute very little to the overall loss of the system.

A colleague has had success with an insulated wire on his roof fed in the middle with an auto-tuner. The coax from the tuner has several type 31 chokes to kill common mode and the coax itself contributes very little to the performance of the system.

On the other hand, such a short antenna as you are using (on the lower bands) fed with RG-58 from a tuner in the shack is expected to have significant losses. If this is the case, moving the tuner outside should be tried.

Taking this to mean that the ATU is at the tx end of the 25' of RG58...

It is challenging with that topology get get good antenna system
efficiency when the monopole is less than about 17% of a wavelength.
Working that backwards, your 2.6m whip is 17% of a wavelenght on 15m
wavelength or 20MHz.

The contributions to poor efficiency are feed line loss under standing
waves, ATU loss, and if the whip is magnetic stainless, conductor losses
in the whip.

RG8 will have lower losses, but the result will be a more challenging
load for the ATU and its losses will increase, consuming some of the
benefit.

You really need to take a system perspective because there is a complex
interaction of the system components.

>
> Any comments on how to hold down feedline losses. One suggestion is

Paralelling two cables reduces Zo to one half, but the matched loss per
metre is the same. The loss under standing waves depends on the actual
load impedance which you probably don't know.

>
> Possibilities?
>

A remote ATU, a longer monopole.

Owen

Yes, the wording is confusing. The antenna is fed with about 25 feet of
RG-58 with the tuner next to the rig in the shack. The cable will be
changed to RG-8 tomorrow assuming that the winds finally die down here in So
Cal.

On 10 and 12 meters the performance is quite acceptable. I'm not the big
signal on the band, but it works well.

I'm hoping to slightly lengthen the antenna and get performance from 17 to
10 meters. Since the tuner to antenna VSWR will be very high, I'm pondering
ways of lowering the loss.

A separate loaded whip is used on 20 and 40 meters.

So far, the experiment has been good, and it is one of the few antenna
configurations that meet the established requirements. (established by the
xyl) :)

Thanks
Wayne

The OP seems to be doing what I did for many years, ie feed an endfed monopole antenna (of undefined length) with coax, and force match it, as required, at the shack end. [I believe it was you, Owen, who pointed out my error in trying to use the graphs showing loss vs SWR when the coax is electrically short (less than a wavelength.]

Although I now have a remote tuner at the antenna feedpoint, I can't say I've noticed an outstanding improvement in performance (although, to be honest, I really haven't really done a lot of operating since I installed the tuner).

If you don't want use a remote tuner at the antenna feedpoint, the impedance at the shack end of the coax will be the antenna feed impedance, transformed by the length of the coax, and also altered by the loss in the coax. Provided the shack-end tuner can be persuaded to match the impedance seen looking into the coax, the system will work tolerably well with low-loss coax.

It is obviously advantageous to use the lowest loss coax you can lay your hands on. As, in cable TV systems, long coaxial trunk lines have now been superseded by optical fibers, I would suggest that a cable TV operator might be persuaded to donate some nice chunky coax (preferably "as thick as a horse's prick", as one of my bosses once described it). Failing that, just go for the best you can get.

If its an autotuner, best place for it is at the base of the vertical.

Way too much time and money is being wasted in the change over from the rg58 coax. Even with a 20 to 1 SWR the rg-58 will loose about 3 db of signal due to the large mismatch. the rg-8 will still loose atleast 1 db. This 'big' gain of 2 db is hardly worth it. More time and money should be put into a beter antenna. Maybe one of the trap type verticals that is 30 or more feet tall. You gain by a beter radiation efficency and at the same time cut the loss in the coax due to the beter match. Even the screwdriver type antenna would probably be much beter. With that you get rid of the losses in the antenna tuner.

Taking this to mean that the ATU is at the tx end of the 25' of RG58...

It is challenging with that topology get get good antenna system
efficiency when the monopole is less than about 17% of a wavelength.
Working that backwards, your 2.6m whip is 17% of a wavelenght on 15m
wavelength or 20MHz.

The contributions to poor efficiency are feed line loss under standing
waves, ATU loss, and if the whip is magnetic stainless, conductor losses
in the whip.

RG8 will have lower losses, but the result will be a more challenging
load for the ATU and its losses will increase, consuming some of the
benefit.

You really need to take a system perspective because there is a complex
interaction of the system components.

>
> Any comments on how to hold down feedline losses. One suggestion is

Paralelling two cables reduces Zo to one half, but the matched loss per
metre is the same. The loss under standing waves depends on the actual
load impedance which you probably don't know.

>
> Possibilities?
>

A remote ATU, a longer monopole.

Owen
****

-
Thanks Owen. As usual, good information.
For clarification, there are two antennas. One is a bugcatcher type whip covering 40, 30, and 20. That part of the "farm" is working well. and requires no tuner.

The other is for 17 through 10 meters and is the one that will be a single short radiator with tuner in the shack. An 8 foot whip is currently used, but the max acceptable length will probably be in the 11 foot range. A longer radiator (than about 11 feet) is not "permitted", and a remote ATU is possible, but not desired. Feedline loss for this antenna was the subject of the original post.

Thanks again.
Wayne

The OP mentioned a 2.5m whip down to 40m. VSWR(50) of such a thing is likely to be around 1000 so your estimates of loss for VSWR(50) are not applicable to that scenario. (Estimating loss based on VSWR is prone to error in any event.)

An NEC model suggests that feedpoint Z might be something like 10-j800. Taking that for example with 25' of RG58, line loss is more like 17dB.

RG213 is better, but it does not solve the fundamental problem that R at the feedpoint is very low, and a large current is required to deliver power. Large currents contribute to high loss in feedlines.

Owen

===

No mention of loading coils, other antennas and you make specific
mention of using this antenna on 40m (QSOs offered as evidence,
notwithstanding that EIRP is probably very low due to extreme line loss
as calculated in another post).

If you can't express the scenario clearly, the advice you get is even
less reliable!

The whole point was that going from rg-58 to rg-8 or the rg-213 or lmr-400
would not make hardly any differant. While the loss may be something like
17 db in the rg-58, it would still not be beter than 3 db going to another
type of 50 ohm coax.

You are right. I should have simply asked "how does one lower real world
transmission line loss when the VSWR is high", and skipped the commentary.

2779. Seeking New FAQ/Intro Maintainers for rec.radio.amateur.*

Years ago I had put up a similar antenna to be able to get onto the
local 10M net. I then as you have tried to tune it up on other bands
after upgrading from Tech+ to General and got similar results to what
you have discribed. Changing the radiator to 5/8 wl on 10M improved
operation of the antenna not so noticably on 10M as it did the other
bands. Good luck, have fun and learn.

Jimmie

So far it has been fun. I've been able to check out the antenna on 10 and
12 and it works well. I need to fix a rig problem before 15 testing. 17 is
working, but propagation hasn't been good enough for much testing.

Tests on 20, 30, and 40 yielded qsos, but with low signal reports. Those
bands have been written off for the tuner/coax/whip. However, I'll try 20
again if I get a longer radiator up.

5/8WL on 10m is ~0.3 WL (> 1/4WL) on 20m so it will have an
inductively reactive feedpoint impedance around 78+j200. A series
capacitor of ~56 pf at the feedpoint on 20m should result in an SWR on
the coax of ~1.5:1.

Something for consideration for lengthing the whip: Buy a 3 or 4 ft 3/8 inch aluminum rod from local hardware store and thread it on both ends with 3/8x24. Use a coupler nut to fit it to the bottom of the whip. I've used this technique with mobile antennas and seems to work fine.

Also, you mentioned the ability to use open wire/ladder line. Wonder if you considered ladder line to a 4:1 balun and then short coax to tuner? I'm not sure that presently with such a short run of coax to the patio you would gain much, but for longer runs, it would definitely be a consideration.

Thanks for the info Cecil. It turns out that a 10m 5/8 would be too long to meet the wife's "requirements".

I haven't gotten into describing the antenna "problem" in detail, but here is a synopsis:
Space is available for 2 verticals to be mounted on top of a metal patio cover, and they should not be prominently visible. That limits the total length of each to about 11-12 feet. A base mounted remote antenna tuner is not desired.

Band coverage is desired for 40 through 10 meter cw. One antenna, a 11 foot bugcatcher, is used on 40/30/20. The other antenna that is being pondered has a configuration of tuner/ 25 ft of coax/11 ft whip, tunable at least from 10 through 17 meters....thus the interest in low feedline loss.

With further consideration it appears that the loss in 25 ft of coax is not a game changer. Experimentation continues, and results are positive so far.

I have one of those too. Not as nice condition though. It was used a lot back in the day, but it still works, and even has an HB-525 still attached to it. I checked to see if there was any interest in this item, and saw it took in $129.26 just for the pack without radio or batteries. Wow.

Don't know about the first question.

Alternatives

o Hot glue filled heat shrink tubing. Readily available at my local pro electronics store.

o a drop of mixed 5 minute epoxy

o a large number of other things available at your LHS or FLAPS. Be creative.

tom
K0TAR

LHS - Local Hardware Store
FLAPS - Friendly Local Auto Parts Store

Hardware stores have slip on caps (of various sizes) that I used to get for my elderly aunt's walker and canes. I have found them to be satisfactory, but change them often because they will deteriorate and begin to leak.

Thanks for the ideas.
The question was prompted because I don't want to take the antenna down for a check or repair, and I don't know how well my readily available materials hold up under UV and heat.

I'll mull this over a bit, and then charge ahead :)

How useful is it to have plastic tip caps on an antenna you cannot reach?

I could understand that you would want a spherical tip end to reduce
the risk of arcing, but it would need to be metallic and would not suffer
from UV or heat.

If the antenna is made of hollow aluminum tubing it keeps rain, snow and
insects out of the tube.

Heat shrink end caps. Thes hold up well in sun light and have glue on
the inside that melts when you apply heat..

Jimmie

It would also prevent the tube from howling or "singing" when the wind
hits just right.

Yes in some posts last week or so, I was talking about a steel whip.
However, I have ordered some telescoping tubing to replace the whip with a
longer radiator. It won't be that difficult to take the antenna up and
down, but at my age, it's better to stay off ladders and roofs :)

Intelligent questions have a better chance of
receiving intelligent answers -- versus receiving QRM.

Is this a vertical whip antenna, a vertical tubing antenna, a vertical
pipe antenna, a vertical tower antenna, or even a vertical wire antenna?
```

Going back to the original post....
"Where does one acquire those slip on tips for vertical antenna elements.
Or
what readily available alternatives are there?"

I don't recall seeing slip on tips for whips, pipes, towers, or wires.
Apparently you have, so I will clarify by saying that it is 3/8 inch tubing.
Is that "intelligent question" enough for you?

Another idea.
Have used this for many years.
Put a small wood dowel inside the element, snug fit, make it flush with the
end of the element.
Dip end of element if "Dip It" or "Liquid Electricians Tape".
Have elements that have been up for lots and lots of years without a
problem.
Heat, water, snow, ice, UV; nothing seems to bother it.

2810. Off Topic Furnace Question ??

Newsgroup: rec.radio.amateur.antenna
Date: 2011-12-16 23:20:26 UTC
From: Tuuk <abraaaa@cadabraaaa.ca>
Message-ID: <_mQGq.3487$aW6.811@newsfe09.iad>
Source record: 3211

Hi

I have the Keeprite 075 condensing gas furnace. Only about 10 years old. Honeywell pro 8000 thermostat. NUGM100EHB1 is the furnace.

My question is what happened all of a sudden yesterday when I think I had a bit too much humidity in the air, why did the furnace fail?

Now when there is a call for heat on the thermostat, what happens is both blowers run only. The exhaust blower venting out runs immediately on start up, the main house blower starts immediately on start up. But no clicking from the honeywell smart valve, no sparking or ignighting beginning or trying. Nothing else is happenening. No gas is going through the valve, no obstructions in either intake or exhaust piping. I just vacuumed everything out, I changed thermostates to the old one, same thing happens. I suspect either the motherboard which has no lights to blink to show alarms, or the gas valve which I had to replace couple years ago, But back then at least the igniters would light up and shut off immediately, told me it was a gas valve issue so replaced that and worked. All else looks clean and I smacked as many relays as I could see, checked all the tubes to see if connections are ok and seems ok. Even when thermostat is turned off, disconnected, when I turn the furnace on it only immediately starts up the both blowers and nothing else, no clicking, no safeties going on and off, no nothing. Anyone here have a suggestion other than hiring an HVAC contracting firm to come in and give me estimates? I know a board is about 50 bucks, easy to replace, gas valve is about 150 easy to replace, what ever sensor should be cheap and easy to replace. Any suggestions as to what to try next?

Thanks Hams, I know this is off topic, but I have gotten good advice from this group before and there are no furnace newsgroups of any kind on my server.
Thanks for any advice or tips or links

Hi

Ya, I googled it a lot, found some information but nothing explaining why the furnace's both fans run immediately with nothing else happening.

Suppose I will try replacing components one by one, I'll go by most replaced components. I can google that.

I tried jumping the high low switches, the vacuum switch, cleaned out the chamber, cant really see the ignighter but that is an easy replacement and might as well after 10 years. I heard they rarely last that long.

Got some excellent advice from this group before, will do it again.

When you say no lights to blink - do you mean it has no lights on the board
to do that
or do you mean there are lights on the board but they do not light up.
If the latter, it would certainly seem to be the board, if the former then,
darn, no help there.
```

Having had a similar problem my first replacement item would be the motherboard.
Normally the vent blower comes on to purge the system for a few seconds, followed of
course by the igniter, then the gas valve and after a short warm up the main blower fan.
As both fans and start at the same time and nothing else is happening I am thinking
the mother board is at fault.
Like you say, easy to replace and not to expensive and from the sound of the problem
I would guess that is a good starting place.
I have a spare board and whenever I have a problem I use it for trouble shooting.
If I replace it and get the same problem, then, I am off in search of what is really
causing the problem.
As a side note, the earlier problem with the gas valve could have also been a motherboard.
If the vent blower starts, then the igniter lights and then shuts down either the motherboard
did not sense igniter heat or it did and then did not send the signal to open the gas valve.
In your case it worked like it should but the valve did not open. It could have been a bad
igniter sensing circuit or a bad valve opening relay however. Just something to keep in mind.
Good luck with your problem.
Not a licensed furnace guy or anything, just have to do it all myself living as far out in the
boonies of northeast Montana as I do. You learn to do this stuff or freeze during the winter.

Check the air intake and exhaust output on the furnace.

If either is clogged, the furnace will start up then shut down.

Also -- how does your system dispose of condensate? Is there a
condensate pump? If it's not working, the system will start up then
shut down when it sense the condensate pump is not working.

When working projects without prior knowledge or experience I try to
use the following approach:
Log observations and my actions on paper
Do what is easy
Do what is cheap
Clean it
Take pictures before disassembly
Determine how it is supposed to work... this is where it gets serious!

This has been the prob with my Mom's gas furnace... the condensate reservoir fills up and trips the float switch because the condensate pump isn't working (or the drain line is frozen in my case). the fans run but no gas, etc

Is there a thermostatic switch on the hot air manifold?

That would be the first thing to check. If not that, then I
would check the induced fan blower system that exhausts the
hot gasses.
You would want to make sure the flue pipe is clear, and
also the little tiny hole that is in the blower housing,
which is inside the nipple where the little usually rubber
hose connects. Many times that little hole will become
plugged and the pressure switch will fail to operate.
You can jump the float switch for a quick test.
You can also jump the pressure switch for a quick test,
but you have to start the furnace cycle first, let the exhaust
fan start running, and then jump the switch.
If you jump the pressure switch first, and then try to cycle the
furnace, it will see it as a bad pressure switch, and it will not
operate.
But in this case, the condensate reservoir is the more likely
culprit. That's a fairly common problem with those.

You're a little early for your unrelated to the group problem of the month. I believe you have posted non-ham radio questions 4 times in as many months. Of the tens of thousands of news groups, THIS is the best place to seek help on gardening, HVAC, etc.? Have you found your solution yet?

If you don't care what others think about you, then your are going about this the wrong way. You need to go to a group with a lot more traffic than this one. Your odds of finding at least one "member" that doesn't mind encouraging off topic posts will be greatly increased. I hear the porno groups are popular these days. Wait, even better are the mp3 music news groups. If it's Hams you want, the UK Ham group (uk.radio.amateur) is brimming with technically proficient people just waiting to assist. That group gets a lot more posts each day than this one.

This is fun, let's do it again next month.

He could do worse, being as I'm qualified to repair such
equipment on a professional basis.. I can fix all kinds
of things, not just radios. :)

With the massive flow of antenna articles I see these days,
it's was lucky he able to get a word in edgewise.. :|

And being as he did post about towers once, at least he's
not a total alien to this small celestial body within the
vast galaxy called usenet.

And he did say he tried to find the applicable groups,
but found no joy. :(

Of course, your informative post was quite valuable to this
group I'm sure. :/

Hummm..

Hi

Thanks for all the advice. And I have tried all those. I took the condensing fan blower out and cleaned out that housing behind it and re-siliconed it. It did have some gunk in there but not enough to cause a clog. But now that is clean and when I reinstalled it the exact same thing happened. What is troubling me is that even if the thermost wires are disconnected from that board what happens is both man blower and exhast blower simply are the only things that run. Instantly. No sequence of events eg blower starting, then ignigters starting then main blower after heat exchangers heats up. None of that. I jumped that float switch and those vacume hoses I sucked and blew through them and I can hear the switches working, but same thing happens, nothing happens with that honeywell smart valve, no gas. I checked all the intake air pipes and exhaust pipes, nothing clogging. While everything leads me to believe it is the board so I bought another for 80 dollars and will replace that board today. I will take a photo of the board and one by one replace those wired and connections and try that. I was hitting those relays on the board and still nothing.

Seems some are upset because of my posts of my antenna and my sauna and garden,,,, well coincedently enough I have in my basement the sauna and steam bath thing I also installed and it was that very night that me and the missis were steaming it up in the sauna and steam bath and I think maybe there was moisture in the air that evening as that was the evening it failed.

To answer a question about the lights, my friend's furnace has the idiot lights where it blinks signifying what has failed, mine has no lights on that board, I think mine was the model before his, mine is about ten years old. I am going to replace this main fan relay board and see if that solves the problem, I can return the board if the same problem remains and start replacing the next part after that until something works right. I replaced the thermostat with the old one and same problem.

Thanks for the advice and tips. As I have said, I know there is a lot of knowledge in this group, I have benefited from it before and will again, as my server doesn't have active newsgroups like HVAC or Furnace or any of the other crazy things I have asked about. Lots of knowledge here, thanks. And i cannot wait until someone asks a question about their furnace, or their sauna rocks, or their tower, or their garden,,, because I will be the first to answer.

Source record: 3226

Ok,

I changed the main fan board, and still the exact same condition happens.

Even though the thermost is off, even disconnected, as soon as I turn the
main toggle switch for my furnace, both main blower fan and exhaust fans
immediately begin and nothing else happens.

I just unplugged on leg from the high limit switch, then one leg from the
low limit switch then both together

Same, nothing.
Any suggestions?

Thanks

I only just saw your post, but before you replace the timer board, check to see if there is a limit switch in the blower compartment, and see if there is a reset for it. If this doesn't work, connect a jumper across it and see if that works. If that doesn't do the trick, look for other limit switches and do the same for those. You may not need to replace the timer board after all.

Let us know what you find out please.

Sorry about the previous duplicate posts, the first one came back as unavailable when I tried to download it myself. That normally only happens when a post expires, but I digress.

Anyway, short the 2 terminals on each limit switch - one switch at a time with the other(s) connected normally. I would start with the blower limit switch. That would be my best guess.

I believe this furnace was made by Heil. I'm out of it now, but I've installed, (and repaired) more of their furnaces and air conditioners over the years than I could count. They are my favorite make. They are the same furnaces that Sears sells, and they also used to be sold under the "Tempstar" brand. That is if they are, as I believe, made by Heil.

Best of luck,

Normally, the blower motor and inducer blower should not start at the same time. I was thinking maybe you had the T-stat fan set to "on" and it was running when you called for heat, or maybe it was running due to a "power off during heat cycle" code. But in that case, the blower would run for appx 90 seconds, go off, and then the inducer fan would come on. This is usually a code "12" on a furnace with winky blinky error lights.

But there is another thing that can cause what you are seeing, and that would be an open solid state hi-limit control. If one of those goes open, the IFC "integrated furnace control" which is the board, will cut the 24 volts to the gas valve circuit and then energize the blower blower, and the induced draft blower. These will stay on until the SS hi-limit closes, and then the heat cycle will restart. So you may well have an open hi-limit switch. Test the two connections with an ohm meter. If the furnace is cold, the hi-limit should show continuity. If not, it's kaput. These are usually in series with the other limits, so check all of them. Some of the ones in series will have little buttons you can press to reset.
A SS hi-limit does not have a reset button. It should close back up on it's own after the furnace cools down. But they can go kaput and stay open.
Some may have thermal fuse links also..

If the hi-limit shows open with an ohm meter,
jump the two wires going to it with a jumper.
If that was the culprit, the furnace should start it's
normal heat cycle, close the pressure switch, and
start the igniter.
You would then need to replace the hi-limit switch.
Don't use the jumper in normal service. EVER!
That is just for testing.

But! You would also want to make sure there is no
problem that is causing high exchanger temps before
calling it a day.
Those can be a dirty filter, failing fan motor,
bad cap to motor, motor running too low a speed,
dirty blower wheel, over firing of the burners
due to excess manifold pressure, or orifice size.
So at this point, I think I would be eyeballing
the limits and the SS hi-limit in particular.
That usually looks like a phenolic wafer board with
two terminals that is often inside the case behind
the IFC.
And don't be afraid to call a tech if you feel you
are getting in over your head. I'd hate to see
you burn your house down due to some overlooked
problem that is causing excess temps.

BTW, you should always diagnose a problem in an
orderly military manner. Don't buy parts until
they are proven bad. Throwing money at a problem
and hoping something sticks can often get expensive
and not cure the problem.
Same thing with cars... :/

Anyway, this gives you a bit more to ponder..

Was reading that.. Actually, that "the hi-limit" is usually
around the heat exchanger to the side of the burners..
Dunno why I said it was behind the IFC, which is usually
in the blower area.. :/ But there are other limits for
the blower too. Most of those have the little reset buttons,
and sometimes there can be one in the back side of the
blower that is hard to see. Most limits have blue wires
going to them I believe. They are all rigged up in series.
So if you see a pair of blue wires going back behind the
blower, there is a limit there mounted on the blower housing.

Bingo

You are absolutely right. There is a reset button hidden between those two terminals in the upper limit switch in that heat chamber.

Wow, nothing I read in my manuals said anything about that reset button. And I paid a technician to come in and diagnose what was wrong, he told me to clean out the condensing housing there, re-silicone that as that may be clogged up but it wasn't and I did that. He also told me he was 99% sure it was a failed board and for him to replace was 300 plus the board, I purchased a board for 80 and did it myself and dam, same problem existed. Now I can return the board (or keep it as it is newer board and allows me now for cooling delay where the old board didn't and the old board didn't have fuses on, the new one does) so newer board is improved but now have back up board so it wasn't the board at all. I paid for a licensed technician to come diagnose after I tried all componenets, and was wrong. Shit happens I guess. Turns out you are exactly right Bob about the limit switch causing both fans to run immediately. after resetting that little button (why didn't that service guy know there was a little reset button hidden in that unit). I bypassed that and must have had the other one closed because it is inline with the smart valve. Wow, what a learning experience.

Anyway, I know more about my furnace than most home owners now, so good learning experience for me and have about 100 dollars worth of extra spare parts incase it fails again.

Excellent advice as usual from you hams. Appreciate every one of your comments, suggestions, tips. I got it working and saved a few hundred dollars but now know more about it than before. A lot more. Very shocked that the licensed service technician furnace guy didn't simply try that reset button. The easiest fix in the world, yet missed it and he would have replaced the board and found the same problem exists then he would have kept trouble shooting and found the relay reset button like I did and charged the home owner a big amount and replaced the board for nothing. Should have been an easy reset fix. Now I know.

Thanks Hams,,, 73s and happy holidays.

Now if I read anyone having issues with their furnace similiar to mine, I am happy to offer advice. Big learning for me. Excellent. (but cost me about 100 bucks but shouldn't have cost me anything).

Thanks again

Excellent. Sorry I didn't see the thread sooner, it would have saved a lot of time and money. You will probably want to keep the board. Most places won't accept returns on electrical parts. It's too easy for someone to swap their defective part for the new one and try to return it. People try that more often than you would believe.

It's not surprising that the "technician" told you it was the timer board. Look at what it cost, and what he was going to charge for it. In most areas, there is no licensing or certification necessary at all for someone to repair furnaces. If someone presents you with an expensive repair estimate, always get a second opinion. It might be worth the price of a service call to discover that you really don't need it after all. Ask family, friends and neighbors who they use, how many times they had to call them, and were they satisfied.

Glad I could be of help.

Some of those boards cost silly $$$$$...Even wholesale price.
I always dread having to tell someone they need a new one,
because it's usually a pretty high bill, just because the
price of the part is so high from many of the manufacturer's.
It's usually the dinky fan relays that go TU if one actually
does go bad.
Some companies seems to be semi reasonable.. But some of the
biggest brands like Lennox, Trane, etc.. Ouch... Often around
$225-$250 wholesale just for the part.
You have to be licensed here, but even that doesn't mean the

guy isn't a crook.. :/
They have some companies here that are so big, and have so much overhead, that they almost have to rip people off to stay in business. I can think of one in particular here locally that I hear lots of complaints about. They have a big monster dispatch center that looks like Mission Control at NASA, lots of overhead, loads of trucks, etc.. And they have expanded to other cities in the state.
They rob nearly everyone they deal with. :(

2835. Antenna Pointing Aid From ARRL

Where to aim the ol' spark-catcher???

"Hams love maps, map software, and map-plications! Here's an online applet to create a simple azimuthal-equisdistant map centered on any location you care to specify." -- ARRL Contest Update

The latest edition of the Update contains this link:

http://hp.vector.co.jp/authors/VA011609/azmeqdist_e/azmeqdist_e.html

The site allows for quite a few options. Click around and play. You can drag the geographic map center with your mouse and you'll see the LAT/LONG numbers change as you do. I see no azimuth ring around the outside but a clever fellow can label his printed-out map.

"Sal"
(KD6VKW)

PS: If, perchance, you don't know about the Windows "Print Screen" key and your ability to paste (and edit) the captured bitmap into the "Paint" program ... well, now you do. On Mac, use "Grab" for much the same thing.

Absolutely right.

I appreciate all the input, yes it would have cost me a lot and for what turned out to simply be a resetting of that limit switch.

Good part is that I learned my furnace mechanically inside and out. Only costs me about 100 and have a spare board now.

But after trying everything I could think of, after bypassing all the safeties and bypassing things I was just perplexed.

Thanks again

The only thing I wonder about is why it tripped the limit..
I'd keep an eye out on it for a while.. Make sure the fan
never quits running when it should be, doesn't start slowing
down from normal speed, filter clean, etc..
Of course, if there is some problem, it will just trip again,
and you might be able to get an idea what is causing it.

I've already listed most of the things that could cause that.
In the majority of cases, it's the blower motor going kaput.
Then again, maybe it was just a fluke.. @#$% happens sometimes..

I said before that I didn't want you to burn your house down,
but actually it's almost impossible with all the safety devices
those things have. So you really don't have much to worry about
if something does cause it to overheat in the future.

Hey, Thanks for the good advice.

I recently installed a sauna and spa on the same floor, it just happened to be that particular evening that the limit switch tripped when I had used those two units so I think I got a lot of humidity and heat in that basement. Then I also had to remove the intake pipe supplying the fresh air from outside because I had to move something else so that pipe was off and it was sucking in air from that room for combustion. Also, the heat supply ducting inspection plate had been removed from that room because I wanted to add some heat into that room. When I feel that intake area near the tripped limit switch, it is very warm. Now that I have re-connected everything it is cold. So maybe those scinarios had direct responsibility for tripping that limit switch. That is what I am thinking. I think too much heat in that chamber caused it to trip. Doing its job. Hasn't tripped yet after about 6 hours of operation on and off.

Thanks again

I find Google Earth much easier to use. Gives distance and heading. You
can also see the satellite pic of the country (if you're curious).

That was probably the problem. Shouldn't have been a severe overheat,
but maybe enough to push it slightly over the edge as far as the limit.
I doubt you will have any more problems if it's run OK so far.

I love Google Earth. I have it on my iMac in the house. In the shack, however, I usually can "hear" the monitor as I tune across the bands, so I normally keep it off. I just installed GE here and it runs nicely (XP, 2.4 GHz, 1 GB).

I don't see the feature to do a range and bearing from Home.

Thanks again Hams

Really appreciate your advice here on this topic. I now know more about my furnace than the licenced quaified repair techinician who I paid to diagnose the problem. That is true because I took the couse HVAC engineering about 20 years ago and spent years doing heat lose heat gain caclulations for industry. But never knew there was a simple little dimple reset button in the stragest place. Dam.

Now I know and there is nothing on this unit I cannot repair myself. Servicing and cleaning is easy.

Sorry I upset a few of the hams, I know it is off topic however there is no groups on my server that are active, this one is so sorry I upset some hams with my off topic question but I know there is a lot of knowledge in this group,,, and I am thankful for that.

73s and happy holidays.

2845. Transportation Security Administration Tool Rules

Newsgroup: rec.radio.amateur.antenna
Date: 2011-12-23 17:44:50 UTC
From: Tom Horne <hornetd@gmail.com>
Message-ID: <2447a9a9-4bb8-4b6c-89b1-2b8766ca24b4@q11g2000vbq.googlegroups.com>

All Hands

Be advised that the TSA considers any tool longer than seven inches in any dimension to be a weapon and they will not allow it in the passenger compartment of a common carrier aircraft. In order to save my One Hundred Twenty Dollar crimper I had to send it to myself by FedEx go back through security and dammed near miss my flight. I was unaware of this rule so the crimper was in my Radio Carry On. I would not want any radio that I was responsible for to go in with the baggage because it would be unlikely to arrive at the destination in working condition. I guess I will have to buy one of those Air Transport Cases to hold all of my tools and pay the extra fifty bucks to check it with most airlines. Security Theater strikes again.

In GE, click Tools and select Ruler. Leave the Ruler dialogue box in Line mode. Put your pointer (which has changed to a square with cross hairs) on your starting location and click. Move your pointer to the destination and click again. The dialogue box will show the distance and heading.

Cheers,
John KD5YI

What type of person takes a job knowing it requires them to treat people
like crap?

Works perfectly. Aiming 34.4 degrees for London, 34.35 for Birmingham. <g>

Thanks.

"Sal"

PS: Merry Christmas & Happy Hanukkah to all.

To ensure traveler's security, transportation security
officers (TSOs) may determine that an item not on the
prohibited items chart is prohibited. In addition, the TSO
may also determine that an item on the permitted chart is
dangerous and therefore may not be brought through the
security checkpoint.

Indeed. I'm always amazed when TSA permits my folding walking cane to be
carried on-board.

A news snippet in today's newspaper tells the story of the TSA taking
a cupcake away from a woman because *the frosting could be dangerous*.

There may be more to The Story -- but I won't be surprised if it's no
more complicated than that.

Hmmmm. I got to thinking about your two bearings. The bearing from
Birmingham to London is 44.54 degrees. I don't see how it is possible to
get those two values from a fixed location.

What have you done wrong or what have I done wrong?

John
